#### Abstract

The subresultant theory for usual commutative polynomials is generalized to linear differential, linear difference and Ore polynomials. The generalization includes the subresultant theorem, the gap structure, and the subresultant algorithm. The subresultant algorithm reduces the coefficient growth in the computation of polynomial remainder sequences without computing coefficient GCDs.

Using the subresultant theorem, we present a characterization of the compatibility of two elements in an Ore polynomial module, and determinant formulas for the greatest common right divisor and least common left multiple of two elements in an Ore polynomial ring. Furthermore, we present a modular algorithm for computing the greatest common right divisor of two Ore polynomials whose coefficient domain is the ring of univariate commutative polynomials over the integers. Experimental results illustrate that this modular algorithm is markedly superior to non-modular ones.

#### Zusammenfassung

Die Subresultanten-Theorie der gewöhnlichen kommutativen Polynome wird auf die linearen Differentialpolynome, Differenzpolynome, und Oreschen Polynome verallgemeinert. Diese Verallgemeinerung enthält den Subresultantensatz, die Spaltstruktur und den Subresultantenalgorithmus. Der Subresultantenalgorithmus reduziert das Wachstum der Koeffizienten in der Berechnung der Polynomrestfolgen, ohne den größten gemeinsamen Teiler der Koeffizienten zu berechnen.

Mit Hilfe des Subresultantensatzes präsentieren wir eine Charakterisierung der Berechenbarkeit von zwei Elementen in einem Oreschen Polynommodul, und entsprechende Determinanten-Formel für die größten gemeinsamen rechten Teiler und für die kleinsten gemeinsamen linken Vielfachen von zwei Elementen in einem Oreschen Ring. Außerdem präsentieren wir einen modularen Algorithmus für die Berechnung des größten gemeinsamen rechten Teilers von zwei Oreschen Polynomen, dessen Koeffizientenbereich der Ring der Polynome in einer Variablen über den ganzen Zahlen ist. Die experimentellen Ergebnisse zeigen, daß dieser modulare Algorithmus deutlich besser ist als nichtmodulare Algorithmen.

# Introduction

## 0.1 Survey of the Thesis

The purpose of this survey is to provide the reader with an outline of this thesis and a summary of the main results. Precise definitions of the terms that we use can be found in the relevant chapters.

The work in this thesis is motivated by applications of various generalizations of the Euclidean algorithm for linear operational polynomials, for example, the characteristic set method for linear differential (difference) polynomials, and algorithms for computing the greatest common right divisor and least common left multiple of two elements of an Ore polynomial ring. We present a subresultant theory for two elements of an Ore polynomial module to avoid the inefficiency of the generalizations of the Euclidean algorithm, which uses pseudo-division. With the help of this subresultant theory, we extend the modular techniques used in the manipulation of algebraic polynomials to linear operational polynomials.

In Chapter 1, we extend Ore polynomial rings to Ore polynomial modules so that both linear homogeneous and inhomogeneous differential (difference) polynomials can be placed in one framework. We then define subresultants and establish a subresultant theory in an Ore polynomial module.

The main results of this chapter are the subresultant theorem (Theorem 1.4.2) and subresultant algorithm (Theorem 1.4.7). The subresultant theorem describes the gap structure of the subresultant sequence of two Ore polynomials. The subresultant algorithm computes the subresultant sequence of the first kind of two Ore polynomials without any GCD-calculation in the coefficient domain.

In Chapter 2, we apply this subresultant theory to three basic problems, namely, deciding the compatibility of two elements of an Ore polynomial module, computing the greatest common right divisor, and computing the least common left multiple of two elements of an Ore polynomial ring. We show that these three problems are closely related to subresultants.

The main results of Chapter 2 include two algorithms (COMP\_t and COMP\_b) for deciding the compatibility of two elements of an Ore polynomial module, and determinant formulas for the greatest common right divisor and least common left multiple of two elements of an Ore polynomial ring (Propositions 2.2.3 and 2.3.3).

In Chapter 3, we present a modular algorithm for computing the greatest common right divisor of two Ore polynomials over  $\mathbf{Z}[t]$ , where  $\mathbf{Z}$  is the set of integers and t is an indeterminate. Experimental results illustrate that the modular algorithm is markedly superior to non-modular ones.

There are three algorithms, namely, GCRD\_e, GCRD\_p, and GCRD\_m in Chapter 3. GCRD\_e computes the evaluation homomorphic images of the monic associate of the greatest common right divisor of two Ore polynomials over  $\mathbf{Z}_p[t]$ , where p is a prime and  $\mathbf{Z}_p$  is the Galois field of p elements. This algorithm hinges on the notion of subresultants. GCRD\_p and GCRD\_m compute the greatest common right divisor of two Ore polynomials over  $\mathbf{Z}_p[t]$  and  $\mathbf{Z}[t]$ , respectively.

# 0.2 Notation and Abbreviations

Throughout the thesis, the sets of positive integers, non-negative integers, integers, and rational numbers are denoted by  $N^+$ , N, Z, and Q, respectively. We abbreviate polynomial remainder sequence as PRS, greatest common right divisor as GCRD, and least common left multiple as LCLM.

## 0.3 Acknowledgments

I am grateful to my thesis advisor, Franz Winkler, for his constant support, kind advice, and excellent lectures.

I thank George Collins for teaching me so much and serving on my thesis committee.

I thank Bruno Buchberger for his selfless dedication to RISC and his lectures on Thinking, Speaking, and Writing.

Much of my interest in this thesis was greatly stimulated by discussions with Hoon Hong, Peter Paule, and Jochen Pfalzgraf.

Many members of RISC helped me to complete my graduate education in one way or another. I appreciate the participants of the computer algebra and combinatorics seminars for their comments on the work in this thesis. Special thanks are due to Mark Encarnación and Josef Schicho for their friendship and help, and for what I learned from them. I also enjoyed working with István Nemes and Kazuhiro Yokoyama.

The agreeable atmosphere in Schloß Hagenberg made my four-year stay possible and fruitful. Not mentioning many other "castle-mates", I would like to thank Christopher Brown, Olga Caprotti, Roberto Pirastu, Karel Stokkermans, Volker Stahl and Emil Volcheck for their valuable help.

I thank Wentsün Wu for initiating me into the subject of computer algebra and encouraging me to choose a thesis topic connected with differential equations.

I participated in the Special Year in Computational Differential Algebra and Algebraic Geometry at the City College of New York in the spring semester, 1995. My thanks go to Francois Boulier, Phyllis Cassidy, Raymond Hoobler, William Keigher, Sally Morrison, Michael Singer, William Sit, and Dongming Wang for their interesting lectures and insightful comments.

When writing the thesis, I received helpful references and information on particular points from Manuel Bronstein, Giuseppa Carra' Ferro, Marc Chardin, Xiaoshan Gao, and Dongming Wang.

Austrian Academic Exchange Service (ÖAD) provided me a scholarship from February, 1992 to December, 1995. EC project PoSSo (ESPRIT III Basic Research Action, project no. 6846 and Fonds zur Förderung der wissenschaftlichen Forschung, project no. P9181-TEC) financially supported my trips for conferences.

# Chapter 1

# A Subresultant Theory for Ore Polynomials

The objective of this chapter is to generalize the subresultant theory for univariate algebraic polynomials to univariate Ore polynomials. The subresultant theory for univariate algebraic polynomials was developed by Collins [8, 9] in order to avoid the high inefficiency of the Euclidean algorithm for computing PRS's. Brown and Traub [3, 4] subsequently improved Collins' results. As the calculation of PRS's is ubiquitous in solving polynomial systems, the algebraic subresultant theory is applicable to many areas such as: real root isolation [13], the computation of Sylvester's resultants [10], computation in algebraic extensions [37], cylindrical algebraic decomposition [11], computer-aided geometric design [30, 31], geometric coding theory [39], and the characteristic set method [23]. Loos [26] used Habicht's approach to present a fresh look at the subresultant theory and introduced the famous picture of the gap structure of a subresultant chain. We refer the reader to [32] for a detailed account of the subresultant theory based on Habicht's approach. Attempts to extend the subresultant theory to multivariate polynomials were also made for different purposes by Gonzàlez-Vega [17] and Mandache [27, 28].

Since various generalizations of the Euclidean algorithm are widely used in linear differential and difference algebra (see, respectively, [35, § 9] and [29, § 12.2]), we naturally want to extend the algebraic subresultant theory to linear differential (difference) polynomials. Subresultants of differential operators were first defined and investigated by Chardin [5]. Chardin claimed that there existed a differential subresultant algorithm for differential operators. Proofs of Habicht's theorem, the subresultant theorem, and the correctness of subresultant algorithm for linear dif-

ferential polynomials are given by the author [24]. When proving the differential subresultant theorem, I observed that the proof had little to do with differentiation. This observation motived me to develop a general subresultant theory for both linear differential and difference polynomials. For this purpose we extend the notion of Ore polynomial rings [33, 2] to Ore polynomial modules so that both homogeneous and inhomogeneous linear differential (difference) polynomials can be placed in one framework. We then define subresultants and establish a subresultant theory in an Ore polynomial module. This subresultant theory will focus on describing the relations among the subresultants of two Ore polynomials and devising efficient algorithms for computing PRS's.

This chapter is organized as follows. In Section 1.1, we present some background materials and discuss our motivation in greater detail. The notion of Ore polynomial modules is defined in Section 1.2. In Section 1.3, we define the subresultants of two Ore polynomials. Section 1.4 is devoted to proving the subresultant theorem and presenting the subresultant algorithm for Ore polynomials.

### 1.1 Background and Motivation

Linear ordinary differential equations are equations of the form

$$a_n(t)\frac{d^n y(t)}{dt^n} + \dots + a_1(t)\frac{dy(t)}{dt} + a_0(t)y(t) = a(t)$$

and linear ordinary difference equations are equations of the form

$$a_n(t)y(t+n) + \cdots + a_1(t)y(t+1) + a_0(t)y(t) = a(t)$$

where y(t), a(t), and each of the  $a_i(t)$ 's are functions of the variable t. If a(t) is identically zero, then these two equations are said to be homogeneous.

We use algebraic language to describe the sets of linear differential equations. Let  $\mathcal{R}$  be a commutative domain and D a derivation operator on  $\mathcal{R}$ . Then there always exists a differential polynomial ring  $(\mathcal{R}\{y\}, D)$  over  $\mathcal{R}$ , where y is a differential indeterminate with respect to D (see [21, p. 70]). The set of linear ordinary differential polynomials is

$$\mathcal{R}\{y\}_l = \{a_n D^n(y) + \dots + a_1 D(y) + a_0 D^0(y) - a \mid a_n, \dots, a_1, a_0, a \in \mathcal{R}, n \in \mathbb{N}\}.$$

It is easy to see that  $\mathcal{R}\{y\}_l$  is a D-module. The set of linear homogeneous ordinary differential polynomials is

$$\mathcal{R}\{y\}_1 = \{a_n D^n(y) + \dots + a_1 D(y) + a_0 D^0(y) \mid a_n, \dots, a_1, a_0 \in \mathcal{R}, n \in \mathbb{N}\}.$$

If  $A = a_n D^n(y) + \cdots + a_1 D(y) + a_0 D^0(y)$  and  $B \in \mathcal{R}\{y\}_1$ , then we define the product of A and B to be

$$(a_n D^n + \dots + a_1 D + a_0 D^0)(B),$$

that is, the image of B under the linear operator  $(a_nD^n + \cdots + a_1D + a_0D^0)$ . Hence,  $\mathcal{R}\{y\}_1$  can be regarded as a (non-commutative) ring. Notice that the multiplication just defined on  $\mathcal{R}\{y\}_1$  is different from the multiplication on the ring  $\mathcal{R}\{y\}$ . Briefly, we have the following inclusions:

$$\mathcal{R}{y}_1 \subset \mathcal{R}{y}_l \subset \mathcal{R}{y}.$$

Both  $\mathcal{R}\{y\}_1$  and  $\mathcal{R}\{y\}_l$  are D-modules. In particular,  $\mathcal{R}\{y\}_1$  can be viewed as a ring.

If E is an injective endomorphism of  $\mathcal{R}$ , then  $\mathcal{R}$  and E form a difference domain (see, [7]). In the same vein, we can define a difference polynomial ring in a difference indeterminate (with respect to E), the E-module of linear difference polynomials, and the E-module of linear homogeneous difference polynomials. Similarly, the E-module of linear homogeneous difference polynomials can be viewed as a (non-commutative) ring.

A fundamental operation on differential (difference) polynomials is pseudo-division (see, respectively, [36, p. 6] and [7, p. 90]). The *D*-module (*E*-module) of linear differential (difference) polynomials is closed under differential (difference) pseudo-division. Hence, we may define pseudo-polynomial remainder sequences and design the differential (difference) Euclidean algorithm in the two modules. The Euclidean algorithm in the *D*-module (*E*-module) of linear differential (difference) polynomials is used to determine the compatibility of two elements of the *D*-module (*E*-module). The Euclidean algorithm in the ring of linear homogeneous differential (difference) polynomials is used to compute greatest common right divisors.

The differential (difference) Euclidean algorithm, which uses pseudo-division, is highly inefficient because the coefficients grow exponentially as the algorithm proceeds. If  $\mathcal{R}$  is a unique factorization domain, then one may easily design the primitive differential (difference) PRS algorithm to minimize coefficient growth. Unfortunately this method requires many coefficient GCD-calculations, which may be very time-consuming.

The purpose of the subresultant theory in this chapter is to reduce coefficient growth in the Euclidean algorithm for Ore polynomials without any coefficient GCD-calculation. Note that linear differential and difference polynomials are just two special instances of Ore polynomials.

### 1.2 Ore Polynomial Modules

Bronstein and Petkovšek [2] observe that Ore polynomial rings [33] may be taken as an appropriate model for studying computational problems for linear homogeneous differential and difference polynomials. Inspired by their observation, we extend Ore polynomial rings to Ore polynomial modules so as to set up a subresultant theory for both linear homogeneous and inhomogeneous differential (difference) polynomials in one fell swoop. We will define Ore polynomial rings and Ore polynomial modules in terms of operators, because we want to introduce pseudo-division without requiring multiplication.

In the rest of this thesis,  $\mathcal{R}$  is a commutative domain and X is an indeterminate over  $\mathcal{R}$ . The algebraic polynomial ring  $\mathcal{R}[X]$  is regarded as the  $\mathcal{R}$ -module  $\bigoplus_{n=0}^{\infty} \mathcal{R}_n$ , where  $\bigoplus$  stands for the direct sum of  $\mathcal{R}$ -modules and  $\mathcal{R}_n = \mathcal{R}$ , for  $n \in \mathbb{N}$ . The power  $X^n$  is understood as the element  $(0 \dots, 0, 1, 0, \dots)$ , whose (n+1)th component is 1 and other components are 0. In particular, we do not identify  $X^0$  with the multiplicative identity of the domain  $\mathcal{R}$ . The additive identity in  $\mathcal{R}[X]$  is denoted by 0. The degree of a polynomial A in  $\mathcal{R}[X]$  is denoted by deg A. The degree of 0 is set to be  $-\infty$ .

This section is organized as follows. In Section 1.2.1, we define Ore operators and Ore polynomial rings. The notion of Ore modules is defined in Section 1.2.2. Pseudo-division for two Ore polynomials is defined in Section 1.2.3.

## 1.2.1 Ore Operators and Ore Polynomial Rings

In this section, we present an equivalent definition of Ore polynomial rings using operators. Most of the results in this section can be found in [33, 2].

**Definition 1.2.1** The mapping  $\Theta$  from  $\mathcal{R}[X]$  to itself is called an *Ore operator* if the following conditions are fulfilled:

- 1.  $\Theta$  is an endomorphism of the additive group  $\mathcal{R}[X]$ .
- 2.  $\Theta(X^n) = X^{n+1}$ , for  $n \in \mathbb{N}$ .
- 3.  $deg \Theta(A) = deg A + 1$ , for  $A \in \mathcal{R}[X]$ .
- 4. (Multiplicative rule) There exist two mappings  $\sigma$  and  $\delta$  from  $\mathcal R$  to itself such that

$$\Theta(rA) = \sigma(r)\Theta(A) + \delta(r)A$$
, for  $r \in \mathcal{R}$  and  $A \in \mathcal{R}[X]$ . (1.1)

The next proposition describes the relation between an Ore operator  $\Theta$  and the two mappings  $\sigma$  and  $\delta$  appearing in the multiplicative rule (1.1).

**Proposition 1.2.1** If  $\Theta$  is an Ore operator on  $\mathcal{R}[X]$  with the multiplicative rule (1.1), then

- 1.  $\sigma$  is an injective endomorphism of the ring  $\mathcal{R}$ ;
- 2.  $\delta$  is an endomorphism of the additive group  $\mathcal{R}$ :
- 3. for all  $r, s \in \mathcal{R}$ ,

$$\delta(rs) = \sigma(r)\delta(s) + \delta(r)s. \tag{1.2}$$

Conversely, if  $\sigma$  and  $\delta$  satisfy the three properties just listed, then there exists a unique Ore operator  $\Theta$  with the multiplicative rule (1.1).

**Proof** If r and s are in  $\mathcal{R}$ , then (1.1) implies that

$$\Theta((r+s)X) = \sigma(r+s)X^{2} + \delta(r+s)X$$

and that

$$\Theta(rX + sX) = (\sigma(r) + \sigma(s))X^{2} + (\delta(r) + \delta(s))X.$$

Thus, both  $\sigma$  and  $\delta$  are distributive with respect to addition. Setting s=0 in either of the above equalities yields  $\Theta(rX)=\sigma(r)X^2+\delta(r)X$ . Then  $\sigma$  is injective by the degree constraint on  $\Theta$ , moreover,  $\sigma(1)=1$  by letting r=1. It remains to show that  $\sigma(rs)=\sigma(r)\sigma(s)$  and (1.2). Again, (1.1) implies that

$$\Theta((rs)X) = \sigma(rs)X^2 + \delta(rs)X \quad \text{and} \quad \Theta(r(sX)) = (\sigma(r)\sigma(s))X^2 + (\sigma(r)\delta(s) + \delta(r)s)X.$$

Comparing the respective coefficients of  $X^2$  and X yields the desired results.

Conversely, assume that  $\sigma$  and  $\delta$  satisfy the three conditions listed in the statement of the proposition. Then  $\delta(1)=0$  by (1.2). Define  $\Theta$  to be the endomorphism of the additive group  $\mathcal{R}[X]$  that sends  $sX^n$  to  $\sigma(s)X^{n+1}+\delta(s)X^n$ , for  $s\in\mathcal{R}$  and  $n\in\mathbb{N}$ . Clearly,  $\Theta(X^n)=X^{n+1}$ , for  $n\in\mathbb{N}$ , and  $\deg\Theta(A)=1+\deg A$ , for  $A\in\mathcal{R}[X]$ . For r and s in  $\mathcal{R}$ , the following calculation verifies (1.1).

$$\begin{split} \Theta\left(r\left(sX^{n}\right)\right) &=& \Theta\left((rs)X^{n}\right) = \sigma(rs)X^{n+1} + \delta(rs)X^{n} \\ &=& \sigma(r)\sigma(s)X^{n+1} + (\sigma(r)\delta(s) + \delta(r)s)X^{n} \quad \text{(by (1.2))} \\ &=& \sigma(r)\left(\sigma(s)X^{n+1} + \delta(s)X^{n}\right) + \delta(r)sX^{n} = \sigma(r)\Theta(sX^{n}) + \delta(r)sX^{n}. \end{split}$$

The uniqueness of  $\Theta$  is evident.

**Remark 1.2.2** If  $\sigma$  and  $\delta$  satisfy (1.2), then  $\delta(1) = 0$ .

If  $\Theta$  is an Ore operator on  $\mathcal{R}[X]$  with the multiplicative rule (1.1), then we call  $\sigma$  the *conjugate* operator and  $\delta$  the pseudo-derivation (with respect to  $\sigma$ ) associated with  $\Theta$ . For  $n \in \mathbb{N}$ , by  $\Theta^n$  we mean the n-fold composition of  $\Theta$ . In particular,  $\Theta^0$  is defined to be the identity mapping. The same convention also applies to  $\sigma^n$  and  $\delta^n$ . If

$$A = a_n X^n + a_{n-1} X^{n-1} + \dots + a_0 X^0$$

is an Ore polynomial in  $\mathcal{R}[X]$ , then  $A(\Theta)$  is understood as the mapping

$$a_n\Theta^n + a_{n-1}\Theta^{n-1} + \cdots + a_0\Theta^0$$
.

The next theorem enables us to introduce multiplication on the free  $\mathcal{R}$ -module  $\mathcal{R}[X]$  via an Ore operator. The following proof is due to Bronstein and Petkovšek [2].

**Theorem 1.2.2** Let  $\Theta$  be an Ore operator on  $\mathcal{R}[X]$  with the conjugate operator  $\sigma$  and pseudo-derivation  $\delta$ . For A and B in  $\mathcal{R}[X]$ , define the product AB of A and B to be  $A(\Theta)(B)$ . Then  $\mathcal{R}[X]$  becomes a domain with the multiplicative identity  $X^0$ .

**Proof** As  $\Theta$  is distributive with respect to addition, we see that

$$A(B+C) = AB + BC$$
 and  $(B+C)A = BA + CA$ ,

for  $A, B, C \in \mathcal{R}[X]$ . Clearly,  $X^0A = A$ . Since  $\Theta(X^0) = X$ ,  $AX^0 = A$ . To verify the associativity of multiplication, we claim that

$$(X^n(rX^m)) A = X^n(rX^mA), \quad \text{for } n, m \in \mathbb{N}, r \in \mathcal{R}, \text{ and } A \in \mathcal{R}[X].$$
 (1.3)

Proof of the Claim. The proof is done by induction on n. Equation (1.3) trivially holds for n = 0. Assume that it holds for n - 1. We compute

$$(X^{n}(rX^{m})) A = \left(X^{n-1}(\sigma(r)X^{m+1} + \delta(r)X^{m})\right) A$$

$$= \left(X^{n-1}\left(\sigma(r)X^{m+1}\right)\right) A + \left(X^{n-1}\left(\delta(r)X^{m}\right)\right) A$$

$$= X^{n-1}(\sigma(r)X^{m+1}A) + X^{n-1}(\delta(r)X^{m}A) \quad \text{(by the induction hypothesis)}$$

$$= X^{n-1}(\sigma(r)X^{m+1}A + \delta(r)X^{m}A)$$

$$= X^{n-1}(\sigma(r)\Theta(X^{m}A) + \delta(r)(X^{m}A))$$

= 
$$X^{n-1}\Theta(r(X^mA))$$
 (by the multiplicative rule (1.1))  
=  $X^{n-1}(X(rX^mA))$   
=  $X^n((rX^m)A)$  (by the induction hypothesis).

This proves our claim.

Write  $A = \sum_{i} a_{i}X^{i}$ ,  $B = \sum_{i} b_{i}X^{i}$ , and  $C = \sum_{j} c_{j}X^{j}$ , where A, B, and C belong to  $\mathcal{R}[X]$ . The following calculation verifies the associative law.

$$\begin{array}{rcl} (BC)A & = & \sum_i \sum_j \left( (b_i X^i (c_j X^j)) A \right) & \text{(by definition)} \\ \\ & = & \sum_i \sum_j b_i X^i (c_j X^j A) & \text{(by the claim)} \\ \\ & = & \sum_i b_i X^i \left( \sum_j c_j X^j A \right) = \sum_i (b_i X^i) (CA) = B(CA) \end{array}$$

With the multiplication defined in this theorem, we call the triple  $(\mathcal{R}[X], \sigma, \delta)$  an *Ore polynomial ring*. The Ore operator  $\Theta$  is omitted in this notation because  $\Theta$  is uniquely determined by  $\sigma$  and  $\delta$ . A fundamental property of the Ore polynomial ring  $\mathcal{R}[X]$  is that

$$\deg AB = \deg A + \deg B, \quad \text{for all } A,B \in \mathcal{R}[X].$$

The following examples illustrate that Ore polynomial rings establish a general mathematical setting for linear (homogeneous) operational polynomials. As a matter of notation, we denote by 1 and 0 the identity and null mappings of  $\mathcal{R}$ , respectively.

**Example 1.2.3** The Ore polynomial ring  $(\mathcal{R}[X], \mathbf{1}, \mathbf{0})$  is the ring of usual commutative polynomials in X over  $\mathcal{R}$ .

**Example 1.2.4** (Differential Operator) If D is a derivation operator on  $\mathcal{R}$ , then D is a pseudoderivation with respect to 1 because D(rs) = rD(s) + D(r)s, for  $r, s \in \mathcal{R}$ . Hence,  $(\mathcal{R}[X], \mathbf{1}, D)$  is the ring with the multiplication given by  $X(rX^0) = rX + D(r)X^0$ , for  $r \in \mathcal{R}$ . This ring is isomorphic to the ring of linear homogeneous differential polynomials in one differential indeterminate over  $\mathcal{R}$ .

Example 1.2.5 (Hilbert's Twist [22]) If E is an injective endomorphism of the domain  $\mathcal{R}$  and  $\delta$  is  $\mathbf{0}$ , then  $\mathbf{0}$  is a pseudo-derivation. Hence,  $(\mathcal{R}[X], E, \mathbf{0})$  is the ring with the multiplication given by  $X(rX^0) = E(r)X$ , for  $r \in \mathcal{R}$ . This ring is isomorphic to the ring of linear homogeneous difference polynomials in one difference indeterminate (with respect to E) over  $\mathcal{R}$ .

**Example 1.2.6** Let K be a field and  $\mathcal{R}$  the usual commutative polynomial ring K[t]. For a non-zero  $h \in K$ , we define  $E_h$  and  $\Delta_h$  by

$$E_h(f(t)) = f(t+h)$$
 and  $\Delta_h(f(t)) = \frac{f(t+h) - f(t)}{h}$ , for all  $f \in \mathcal{R}$ .

An easy calculation shows that  $\Delta_h(fg) = E_h(f)\Delta_h(g) + \Delta_h(f)g$ , for  $f, g \in \mathcal{R}$ . Thus,  $(\mathcal{R}[X], E_h, \Delta_h)$  is the ring with the multiplication given by  $X(rX^0) = E_h(r)X + \Delta_h(r)X^0$ , for all  $r \in \mathcal{R}$ .

**Example 1.2.7** (q-Differential Operator [34]) Let K be a field and  $\mathcal{R}$  the formal power series ring K[[t]]. For  $q \in K$  with  $q \neq 0, 1$ , we define two operators  $E_q$  and  $\Delta_q$  by

$$E_q(f(t)) = f(qt) \quad \text{and} \quad \Delta_q(f(t)) = \frac{f(qt) - f(t)}{qt - t}, \quad \text{ for all } f(t) \in \mathcal{R}.$$

It is easy to verify that  $\Delta_q(fg) = E_q(f)\Delta_q(g) + \Delta_q(f)g$ , for all  $f, g \in \mathcal{R}$ . Hence,  $(\mathcal{R}[X], E_q, \Delta_q)$  is the ring with the multiplication given by  $X(fX^0) = E_q(f)X + \Delta_q(f)X^0$ , for all  $f \in \mathcal{R}$ .

We refer the interested reader to Chyzak [6] for more examples of Ore polynomial rings.

#### 1.2.2 Ore Polynomial Modules

To establish a single subresultant theory for both homogeneous and inhomogeneous linear differential (difference) polynomials, we use the  $\mathcal{R}$ -module  $\mathcal{R}[X] \oplus \mathcal{R}$ . We define the *degree* of an element  $A \oplus a$  of  $\mathcal{R}[X] \oplus \mathcal{R}$  to be the degree of A if A is nonzero, the degree of  $0 \oplus a$  to be -1 if a is nonzero, and the degree of  $0 \oplus 0$  to be  $-\infty$ . The degree of  $A \oplus a$  is denoted by  $\deg(A \oplus a)$ . The additive identity  $0 \oplus 0$  of the module  $\mathcal{R}[X] \oplus \mathcal{R}$  is denoted by 0.

**Definition 1.2.8** An endomorphism  $\Theta$  of the additive group  $\mathcal{R}[X] \oplus \mathcal{R}$  is said to be an *Ore operator* on  $\mathcal{R}[X] \oplus \mathcal{R}$  if the following hold:

- 1.  $\Theta$  restricted to  $\mathcal{R}[X]$  is an Ore operator on  $\mathcal{R}[X]$ , with the conjugate operator  $\sigma$  and pseudo-derivation  $\delta$ .
- 2. For every  $r \in \mathcal{R}$ ,  $\Theta(0 \oplus r) \in 0 \oplus \mathcal{R}$ .
- 3. (Multiplicative rule) For every  $r \in \mathcal{R}$  and  $A \oplus a \in \mathcal{R}[X] \oplus \mathcal{R}$ ,

$$\Theta(r(A \oplus a)) = \sigma(r)\Theta(A \oplus a) + \delta(r)(A \oplus a). \tag{1.4}$$

The quadruple  $(\mathcal{R}[X] \oplus \mathcal{R}, \Theta, \sigma, \delta)$  is called an *Ore polynomial module* whose elements are called *Ore polynomials*.

For an Ore polynomial ring  $(\mathcal{R}[X], \sigma, \delta)$ , there is a unique Ore operator  $\Theta$  on  $\mathcal{R}[X]$  such that equation (1.1) holds. We can extend  $\Theta$  to  $\mathcal{R}[X] \oplus \mathcal{R}$  by the next proposition.

**Proposition 1.2.3** If  $\Theta$  is an Ore operator on  $\mathcal{R}[X]$ , with the conjugate operator  $\sigma$  and pseudo-derivation  $\delta$ , then the mapping

$$\Theta_1: \mathcal{R}[X] \oplus \mathcal{R} \longrightarrow \mathcal{R}[X] \oplus \mathcal{R}$$

$$A \oplus a \mapsto \Theta(A) \oplus \delta(a)$$

is an Ore operator on  $\mathcal{R}[X] \oplus \mathcal{R}$ . If, moreover,  $\delta$  is  $\mathbf{0}$ , then the mapping

$$\Theta_2: \mathcal{R}[X] \oplus \mathcal{R} \longrightarrow \mathcal{R}[X] \oplus \mathcal{R}$$

$$A \oplus a \mapsto \Theta(A) \oplus \sigma(a),$$

is an Ore operator on  $\mathcal{R}[X] \oplus \mathcal{R}$ .

**Proof** It suffices to verify that both  $\Theta_1$  and  $\Theta_2$  are subject to the respective multiplicative rules. If  $A \oplus a$  is in  $\mathcal{R}[X] \oplus \mathcal{R}$  and r in  $\mathcal{R}$ , then

$$\Theta_{1}(r(A \oplus a)) = \Theta_{1}((rA) \oplus (ra)) = \Theta(rA) \oplus \delta(ra) = 
= (\sigma(r)\Theta(A) + \delta(a)A) \oplus \delta(ra) \text{ (by (1.1))} 
= (\sigma(r)\Theta(A) + \delta(r)A) \oplus (\sigma(r)\delta(a) + \delta(r)a) \text{ (by (1.2))} 
= \sigma(r)\Theta(A) \oplus \sigma(r)\delta(a) + \delta(r)A \oplus \delta(r)a 
= \sigma(r)(\Theta(A) \oplus \delta(a)) + \delta(r)(A \oplus a) 
= \sigma(r)\Theta_{1}(A \oplus a) + \delta(r)(A \oplus a).$$

This proves the first assertion. If  $\delta$  is the null mapping, then

$$\Theta_2(r(A \oplus a)) = \Theta_2((rA) \oplus (ra)) = \Theta(rA) \oplus \sigma(ra) = \sigma(r)\Theta(A) \oplus \sigma(r)\sigma(a) = \sigma(r)\Theta_2(A \oplus a). \quad \Box$$

**Example 1.2.9** Let D be a differential operator on  $\mathcal{R}$ . Define the Ore operator  $\Theta$  on  $\mathcal{R}[X] \oplus \mathcal{R}$  to be such that  $\Theta(rX^n) = rX^{n+1} + D(r)X^n$  and  $\Theta(0 \oplus r) = 0 \oplus D(r)$ , for all  $r \in \mathcal{R}$  and  $n \in \mathbb{N}$ . Let Y be a differential indeterminate (with respect to D) over  $\mathcal{R}$ . Define the mapping

$$\phi: \qquad \mathcal{R}\{Y\}_l \qquad \longrightarrow \qquad \mathcal{R}[X] \oplus \mathcal{R}$$
$$\left(\sum_{i=0}^n a_i(D^iY)\right) + a \quad \mapsto \quad \left(\sum_{i=0}^n a_iX^i\right) \oplus a.$$

Then  $\phi$  is an  $\mathcal{R}$ -module isomorphism such that the diagram below commutes.

$$\mathcal{R}\{Y\}_{l} \stackrel{\phi}{\longrightarrow} \mathcal{R}[X] \oplus \mathcal{R}$$

$$\downarrow D \qquad \qquad \downarrow \Theta$$

$$\mathcal{R}\{Y\}_{l} \stackrel{\phi}{\longrightarrow} \mathcal{R}[X] \oplus \mathcal{R}$$

**Example 1.2.10** Let E be a shift operator on  $\mathcal{R}$ . Define the Ore operator  $\Theta$  on  $\mathcal{R}[X] \oplus \mathcal{R}$  to be such that  $\Theta(rX^n) = E(r)X^{n+1}$  and  $\Theta(0 \oplus r) = 0 \oplus E(r)$ , for all  $r \in \mathcal{R}$  and  $n \in \mathbb{N}$ . Let Y be a difference indeterminate (with respect to E) over  $\mathcal{R}$ . Denote by  $\mathcal{R}\{Y\}_l$  the E-module of linear difference polynomials in Y over  $\mathcal{R}$ . Define the mapping

$$\phi: \qquad \mathcal{R}\{Y\}_l \qquad \longrightarrow \qquad \mathcal{R}[X] \oplus \mathcal{R}$$
$$\left(\sum_{i=0}^n a_i(E^iY)\right) + a \quad \mapsto \quad \left(\sum_{i=0}^n a_iX^i\right) \oplus a.$$

Then  $\phi$  is an  $\mathcal{R}$ -module isomorphism such that the following diagram commutes.

$$\mathcal{R}\{Y\}_{l} \stackrel{\phi}{\longrightarrow} \mathcal{R}[X] \oplus \mathcal{R}$$

$$\downarrow E \qquad \qquad \downarrow \Theta$$

$$\mathcal{R}\{Y\}_{l} \stackrel{\phi}{\longrightarrow} \mathcal{R}[X] \oplus \mathcal{R}$$

**Example 1.2.11** Let  $\mathcal{R}$ ,  $E_q$ , and  $\Delta_q$  be the same as in Example 1.2.7. Define the Ore operator  $\Theta$  on  $\mathcal{R}[X] \oplus \mathcal{R}$  to be such that  $\Theta(rX^n) = E_q(r)X^{n+1} + \Delta_q(r)X^n$  and  $\Theta(0 \oplus r) = 0 \oplus \Delta_q(r)$ , for all  $r \in \mathcal{R}$  and  $n \in \mathbb{N}$ . Then the Ore polynomial module  $(\mathcal{R}[X] \oplus \mathcal{R}, \Theta, E_q, \Delta_q)$  can be regarded as the  $\mathcal{R}$ -module of linear q-differential polynomials in a  $\Delta_q$ -indeterminate.

Notation In the remainder of this chapter,  $(\mathcal{R}[X] \oplus \mathcal{R}, \Theta, \sigma, \delta)$  is assumed to be an Ore polynomial module and simply denoted by  $\mathcal{R}[X] \oplus \mathcal{R}$ . When there is no ambiguity, we denote  $\Theta(A)$ ,  $\sigma(r)$ , and  $\delta(r)$ , respectively, by  $\Theta A$ ,  $\sigma r$ , and  $\delta r$ . By  $\delta \sigma$  it is understood as the composition of  $\sigma$  and  $\delta$ . The same also applies to  $\sigma \delta$ .

The next lemma can be regarded as an extension of the Leibniz rule in calculus.

**Lemma 1.2.4** For r in  $\mathcal{R}$ , A in  $\mathcal{R}[X] \oplus \mathcal{R}$ , and n in  $\mathbb{N}^+$ ,  $(\Theta^n(rA) - (\sigma^n r)\Theta^n A)$  is an  $\mathcal{R}$ -linear combination of  $\Theta^{n-1}A$ , ...,  $\Theta A$ , A.

**Proof** If n = 1, then  $\Theta(rA) - (\sigma r)\Theta A = (\delta r)A$  by the multiplicative rule (1.4). Suppose that the lemma holds for n - 1. Then

$$\Theta^{n-1}(rA) - (\sigma^{n-1}r)\Theta^{n-1}A = \sum_{i=0}^{n-2} r_i \Theta^i A,$$

where  $r_i$  belongs to  $\mathcal{R}$ , for  $i=0, 1, \ldots, n-2$ . Applying  $\Theta$  to both sides of the above equality yields the lemma.

Lemma 1.2.4 is referred as the extended Leibniz rule and will be frequently used in the sequel.

If a submodule  $\mathcal{M}$  of  $\mathcal{R}[X] \oplus \mathcal{R}$  has the property that  $\Theta(\mathcal{M}) \subset \mathcal{M}$ , then  $\mathcal{M}$  is called a  $\Theta$ -submodule. If  $\mathcal{N}$  is a subset of  $\mathcal{R}[X] \oplus \mathcal{R}$ , then the multiplicative rule (1.4) implies that the smallest  $\Theta$ -submodule containing  $\mathcal{N}$  is the submodule  $[\mathcal{N}]$  generated by all the elements of  $\Theta(\mathcal{N})$ , which we call the  $\Theta$ -submodule generated by  $\mathcal{N}$ . Two elements A and B of  $\mathcal{R}[X] \oplus \mathcal{R}$  are said to be  $\Theta$ -compatible if the  $\Theta$ -submodule [A,B] generated by A and B does not contain any element of degree -1. Clearly,  $\Theta$  on  $\mathcal{R}[X] \oplus \mathcal{R}$  can be regarded as an Ore operator on  $\mathcal{R}[X]$  via the canonical projection from  $\mathcal{R}[X] \oplus \mathcal{R}$  to  $\mathcal{R}[X]$ . Thus, we also call  $\Theta$  the Ore operator on  $\mathcal{R}[X]$ . The  $\Theta$ -submodule  $\mathcal{R}[X] \oplus 0$  is simply denoted by  $\mathcal{R}[X]$ . The notion of  $\Theta$ -submodules is a general setting for linear differential and difference submodules, and left ideals of an Ore polynomial ring.

#### 1.2.3 Pseudo-Remainders and Polynomial Remainder Sequences

In this section, we define pseudo-division and polynomial remainder sequences. To simplify the notation that will be used later, we extend the following factorial notation [29, p. 25].

**Definition 1.2.12** For n in  $\mathbb{N}^+$  and r in  $\mathcal{R}$ , the nth  $\sigma$ -factorial of r is defined to be the product

$$\prod_{i=0}^{n-1} \sigma^i r,$$

which is denoted by  $r^{[n]}$ . In addition,  $r^{[0]}$  is set to be 1.

**Lemma 1.2.5** If  $r, s \in \mathcal{R}$ , and  $m, n \in \mathbb{N}$ , then

1. 
$$(rs)^{[m]} = r^{[m]}s^{[m]}$$
,

2. 
$$r^{[m+n]} = r^{[m]} (\sigma^m r)^{[n]}$$
,

3. 
$$(r^{[m]})^{[n]} = (r^{[n]})^{[m]}$$
,

4. 
$$r^{[m+1][n+1]} = r^{[m+n+1]} (\sigma r)^{[m][n]}$$
.

**Proof** The first and second assertions are immediate from Definition 1.2.12. The third assertion is proved by the following calculation:

$$(r^{[m]})^{[n]} = \prod_{j=0}^{n-1} \sigma^j \left( \prod_{i=0}^{m-1} \sigma^i r \right) = \prod_{j=0}^{n-1} \prod_{i=0}^{m-1} \sigma^{i+j} r = \prod_{i=0}^{m-1} \sigma^i \left( \prod_{j=0}^{n-1} \sigma^j r \right) = (r^{[n]})^{[m]}.$$

We calculate

$$r^{[m+1][n+1]} = \prod_{i=0}^n \sigma^i \left( r^{[m+1]} \right) = \prod_{i=0}^n \sigma^i \left( r(\sigma r)^{[m]} \right) = r^{[n+1]} (\sigma r)^{[n+1][m]} = r^{[n+1]} (\sigma r)^{[n][m]} (\sigma^{n+1} r)^{[m]}.$$

The last assertion is then proved by the equality  $r^{[m+n+1]} = r^{[n+1]} (\sigma^{n+1} r)^{[m]}$ .

If  $P \oplus p$  belongs to  $\mathcal{R}[X] \oplus \mathcal{R}$  and P is nonzero, then the leading coefficient of P is also called the leading coefficient of  $P \oplus p$ , and denoted by  $lc(P \oplus p)$ .

**Definition 1.2.13** Let A and B be in  $\mathcal{R}[X] \oplus \mathcal{R}$ , with respective degrees m and n, where  $n \geq 0$ . A pseudo-remainder of A and B is defined to be either A, if m < n; or  $C \in \mathcal{R}[X] \oplus \mathcal{R}$  such that  $\deg C < \deg B$  and

$$\left(\prod_{i=0}^{m-n} \operatorname{lc}(\Theta^{i}B)\right) A = \sum_{i=0}^{m-n} r_{i}\Theta^{i}B + C, \tag{1.5}$$

where  $r_i$  belongs to  $\mathcal{R}$ , for i = 0, 1, ..., m - n.

The pseudo-remainder, as defined in equation (1.5), can be computed by a process analogous to the algebraic pseudo-division. As  $\deg(\Theta^{i+1}B) = \deg(\Theta^iB) + 1$ , for all  $i \in \mathbb{N}$ , the pseudo-remainder of A and B is unique. We denote the pseudo-remainder of A and B by  $\operatorname{prem}(A,B)$ .

**Lemma 1.2.6** If B is a non-zero polynomial in  $\mathcal{R}[X] \oplus \mathcal{R}$ , then  $lc(\Theta^m B) = \sigma^m lc(B)$ , for  $m \in \mathbb{N}^+$ .

**Proof** If  $B = (b_n X^n + \cdots + b_1 X + b_0) \oplus b$ , then

$$\Theta B = (\sigma b_n) X^{n+1} + \text{ terms of degree lower than } (n+1)$$

by the multiplicative rule (1.4), so  $lc(\Theta B) = \sigma lc(B)$ . The lemma then follows by induction on m.  $\square$ 

Corollary 1.2.7 If A and B are the same as in Definition 1.2.13, then equation (1.5) can be rewritten as

$$lc(B)^{[m-n+1]}A = \sum_{i=0}^{m-n} r_i \Theta^i B + prem(A, B).$$
 (1.6)

**Proof** It is immediate from (1.5) and Lemma 1.2.6.

We call (1.6) the pseudo-remainder formula. If A and B are in  $\mathcal{R}[X]$ , then (1.6) can be written as:

$$lc(B)^{[m-n+1]}A = QB + prem(A, B),$$

where Q is in  $\mathcal{R}[X]$ , since  $\mathcal{R}[X]$  is a ring. We call Q the left pseudo-quotient of A and B.

**Example 1.2.14** Let  $(\mathcal{R}[X] \oplus \mathcal{R}, \Theta, \mathbf{1}, D)$  be the same as in Example 1.2.9. Then equation (1.6) gives us the pseudo-remainder formula for two linear differential polynomials, that is,

$$lc(B)^{m-n+1}A = \sum_{i=0}^{m-n} r_i \Theta^i B + prem(A, B).$$

Let  $(\mathcal{R}[X] \oplus \mathcal{R}, \Theta, E, \mathbf{0})$  be the same as in Example 1.2.10. Then equation (1.6) specializes to the pseudo-remainder formula for two linear difference polynomials, that is,

$$lc(B)^{[m-n+1]}A = \sum_{i=0}^{m-n} r_i \Theta^i B + prem(A, B).$$

Similarly, we can obtain the pseudo-remainder formulas for linear  $\Delta_h$ - and  $\Delta_q$ -polynomials.

For A and B in  $\mathcal{R}[X] \oplus \mathcal{R}$ , A and B are similar over  $\mathcal{R}$   $(A \sim_{\mathcal{R}} B)$  if there exist non-zero r and s in  $\mathcal{R}$  such that rA = sB. For  $A_1, A_2 \in \mathcal{R}[X] \oplus \mathcal{R}$  with  $\deg(A_1) \geq \deg(A_2) \geq 0$ , let

$$A_1, A_2, \dots, A_k \tag{1.7}$$

be a sequence of non-zero elements of  $\mathcal{R}[X] \oplus \mathcal{R}$  such that  $A_i \sim_{\mathcal{R}} \operatorname{prem}(A_{i-2}, A_{i-1})$ , for  $i = 3, \ldots k$ , and either  $\deg(A_k) < 0$  or  $\operatorname{prem}(A_{k-1}, A_k) = 0$ . Such a sequence is called a PRS of  $A_1$  and  $A_2$ . If  $A_i = \operatorname{prem}(A_{i-2}, A_{i-1})$ , for  $i = 3, \ldots, k$ , then the sequence (1.7) is said to be Euclidean. If  $\mathcal{R}$  is a unique factorization domain and each of the  $A_i$ 's (i > 2) given in (1.7) is primitive, then this sequence is said to be primitive. From the definition, it follows that there exist non-zero  $r_i$  and  $s_i$  in  $\mathcal{R}$  such that  $r_iA_{i-2} - s_iA_i \in [A_{i-1}]$ , for  $i = 3, \ldots, k$ . Just as in the algebraic case,  $A_1$  and  $A_2$  are  $\Theta$ -compatible if and only if  $\deg(A_k) \geq 0$ .

## 1.3 Subresultants of Two Ore Polynomials

In this section, we define the subresultants of two Ore polynomials. Algebraic and differential subresultants are two special instances of our general definition. We review determinant polynomials (see, [26, 32]) in Section 1.3.1. The definition of subresultants is given in Section 1.3.2. Section 1.3.3 is devoted to presenting the row-reduction formula for subresultants. This formula is used to prove the subresultant theorem in Section 1.4.

Throughout the remainder of this chapter, an Ore polynomial A with degree n is written as

$$A = a_n X^n + \dots + a_0 X^0 + a_{-1} X^{-1}.$$

#### 1.3.1 Determinant Polynomials

**Definition 1.3.1** Let M be an  $r \times c$  matrix with entries in  $\mathcal{R}$ . If  $r \leq c$ , then the *determinant* polynomial of M is defined to be

$$\mid M \mid = \sum_{i=-1}^{c-r-1} \det(M_i) X^i,$$

where  $M_i$  is the  $r \times r$  matrix whose first (r-1) columns are the first (r-1) columns of M and whose last column is the (c-i-1)th column of M, for  $i=-1, 0, \ldots, c-r-1$ .

The polynomial |M| just defined is nothing but DetPol(M) (see, [32, p. 241]) divided by X. Let

$$A: A_1, A_2, \dots, A_m \tag{1.8}$$

be a sequence in  $\mathcal{R}[X] \oplus \mathcal{R}$ . We denote by deg  $\mathcal{A}$  the maximum of the degrees of the members in  $\mathcal{A}$ . Let deg  $\mathcal{A} = n > -1$  and write  $A_i$  as

$$A_i = \sum_{j=-1}^n a_{ij} X^j, \quad (1 \le i \le m)$$
 (1.9)

where each of the  $a_{ij}$ 's belongs to  $\mathcal{R}$ . The matrix associated with  $\mathcal{A}$  is defined to be the  $m \times (n+2)$  matrix whose entry in the *i*th row and *j*th column is the coefficient of  $X^{n+1-j}$  in  $A_i$ , for  $i=1, \ldots, m$ , and  $j=1, \ldots, n+2$ . In other words, the matrix associated with  $\mathcal{A}$  is

$$\begin{pmatrix} a_{1n} & a_{1,n-1} & \cdots & a_{10} & a_{1,-1} \\ a_{2n} & a_{2,n-1} & \cdots & a_{20} & a_{2,-1} \\ \cdots & \cdots & \cdots & \cdots \\ a_{mn} & a_{m,n-1} & \cdots & a_{m0} & a_{m,-1} \end{pmatrix}.$$

This matrix is denoted by  $mat(A_1, A_2, ... A_m)$  or mat(A).

**Definition 1.3.2** The sequence  $\mathcal{A}$  given in (1.8) is said to be determinantal if  $m \leq n+2$ . If  $\mathcal{A}$  is determinantal, then the determinant polynomial of  $\mathcal{A}$  is defined to be  $|\operatorname{mat}(\mathcal{A})|$ . The determinant polynomial of  $\mathcal{A}$  is denoted by  $|\mathcal{A}|$ .

**Convention** In the rest of this section, the sequence A given in (1.8) is always a determinantal sequence of degree n.

**Remark 1.3.3** By the determinant of the  $(m \times m)$  matrix

$$N = \begin{pmatrix} a_{1n} & a_{1,n-1} & \cdots & a_{1,n-m+2} & A_1 \\ a_{2n} & a_{2,n-1} & \cdots & a_{2,n-m+2} & A_2 \\ & \cdots & & \cdots & & \cdots \\ a_{m-1,n} & a_{m-1,n-1} & \cdots & a_{m-1,n-m+2} & A_{m-1} \\ & & & & & & \\ a_{mn} & a_{m,n-1} & \cdots & a_{m,n-m+2} & A_m \end{pmatrix}$$

we mean the sum

$$\sum_{k=1}^{m} (-1)^{k+m} \det(N_k) A_k,$$

where  $N_k$  is the  $(m-1) \times (m-1)$  submatrix obtained from deleting the kth row and the last column of N. One sees that this definition is just the expansion of  $\det(M)$  by its last column. However, our remark is necessary because the  $a_{kj}$ 's are in  $\mathcal{R}$  while the  $A_k$ 's are in  $\mathcal{R}[X] \oplus \mathcal{R}$ .

The following lemmas provide some useful properties of determinant polynomials.

**Lemma 1.3.1** With the notation used in Remark 1.3.3, we have  $|A| = \det(N)$ . In particular, |A| is an R-linear combination of the members of A.

**Proof** It is immediate from Remark 1.3.3 and the formula for expanding a determinant by a column.

Lemma 1.3.2 The determinant polynomial of a matrix is a multilinear alternating function of rows.

**Proof** See [32, pp. 242–243].

**Lemma 1.3.3** Let r be a non-zero element of  $\mathcal{R}$ , A an element of  $\mathcal{R}[X] \oplus \mathcal{R}$ , and k a non-negative integer. If

$$H = |\dots, \Theta^k(rA), \Theta^{k-1}(rA), \dots, \Theta(rA), rA, \dots|,$$

then

$$H = r^{[k+1]} \mid \dots, \Theta^k A, \Theta^{k-1} A, \dots, \Theta A, A, \dots \mid .$$

**Proof** We proceed by induction on k. The lemma is trivial when k=0. Assume that k>0 and that the lemma is true for k-1. Then

$$H = r^{[k]} \mid \dots, \Theta^k(rA), \Theta^{k-1}A, \dots, \Theta A, A, \dots \mid .$$

It follows from the extended Leibniz rule (Lemma 1.2.4) that the polynomial  $(\sigma^k r)\Theta^k A - \Theta^k (rA)$ is an  $\mathcal{R}$ -linear combination of  $\Theta^{k-1}A$ ,  $\Theta^{k-2}A$ , ...,  $\Theta A$ , A. Thus, we may replace  $\Theta^k(rA)$  in the above determinant polynomial by  $(\sigma^k r)(\Theta^k A)$ , according to Lemma 1.3.2. 

At last, we extend the techniques for expanding triangular determinants to determinant polynomials.

#### Lemma 1.3.4 Let

$$\operatorname{mat}(\mathcal{A}) = \begin{pmatrix} a_{1n} & a_{1,n-1} & \cdots & \cdots & \cdots & \cdots & a_{10} & a_{1,-1} \\ 0 & a_{2,n-1} & \cdots \\ \vdots & \vdots \\ 0 & \cdots & 0 & a_{k-1,n+2-k} & a_{k-1,n+1-k} & \cdots & a_{k-1,0} & a_{k-1,-1} \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & 0 & 0 & a_{k,n+1-k} & \cdots & a_{k0} & a_{k,-1} \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & 0 & 0 & a_{m-1,n+1-k} & \cdots & a_{m0} & a_{m-1,-1} \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & 0 & 0 & a_{m,n+1-k} & \cdots & a_{m0} & a_{m,-1} \end{pmatrix}$$

1. If k < m, then

$$|\mathcal{A}| = \begin{cases} \left(\prod_{i=1}^{k-1} \operatorname{lc}(A_i)\right) \mid A_k, \dots, A_m \mid & \text{if deg } A_i = n+1-i, \text{ for all } i \text{ with } 2 \leq i \leq k-1, \text{ and} \\ & \deg A_j = n+1-k, \text{ for some } j \text{ with } k \leq j \leq m, \\ 0 & \text{otherwise.} \end{cases}$$

2. If k = m, then

$$\mid \mathcal{A} \mid = \begin{cases} \left( \prod_{i=1}^{m-1} \operatorname{lc}(A_i) \right) A_m & \text{if deg } A_i = n+1-i, \text{ for all } i \text{ with } 2 \leq i \leq m-1, \\ 0 & \text{otherwise.} \end{cases}$$

Proof By Definition 1.3.1 and Remark 1.3.3, we have

$$|A| = \left(\prod_{i=1}^{k-1} a_{i,n+1-i}\right) \det \begin{pmatrix} a_{k,n+1-k} & \cdots & a_{k,n-m+2} & A_k \\ \cdots & \cdots & \cdots & \cdots \\ a_{m-1,n+1-k} & \cdots & a_{m-1,n-m+2} & A_{m-1} \\ a_{m,n+1-k} & \cdots & a_{m,n-m+2} & A_m \end{pmatrix}. \tag{1.10}$$

Let k < m. If there is an integer i such that  $2 \le i \le k-1$  and  $\deg A_i < n+1-i$ , then  $a_{i,n+1-i} = 0$ , so  $|\mathcal{A}| = 0$  by (1.10). If  $\deg A_j < n+1-k$ , for all j such that  $k \le j \le m$ , then the determinant in the right-hand side of (1.10) is zero, and so is  $|\mathcal{A}|$ . If  $a_{i,n+1-i} \ne 0$ , for all i such that  $2 \le i \le k-1$ , and  $a_{j,n+1-j} \ne 0$ , for some j such that  $k \le j \le m$ , then (1.10) becomes

$$|A| = \left(\prod_{i=1}^{k-1} \operatorname{lc}(A_i)\right) |A_k, A_{k+1}, \ldots, A_m|.$$

If k = m, then equation (1.10) becomes  $|A| = \left(\prod_{i=1}^{m-1} a_{i,n+1-i}\right) A_m$ .

#### 1.3.2 Definition of Subresultants

**Definition 1.3.4** Let A and B be polynomials in  $\mathcal{R}[X] \oplus \mathcal{R}$  with respective degrees m and n, where  $m \geq n \geq 0$ . For  $j = n - 1, n - 2, \ldots, 0, -1$ , we define the jth subresultant of A and B to be the determinant polynomial

$$\operatorname{sres}_{j}(A,B) = |\underbrace{\Theta^{n-j-1}A, \ldots, \Theta A, A}_{n-j}, \underbrace{\Theta^{m-j-1}B, \ldots, \Theta B, B}_{m-j}|,$$

The nth subresultant of A and B is defined to be B. The sequence

$$S(A, B) : A, B, sres_{n-1}(A, B), ..., sres_{-1}(A, B)$$

is called the subresultant sequence of A and B.

Example 1.3.5 Let  $A = a_2X^2 + a_1X + a_0X^0 + a_{-1}X^{-1}$  and  $B = b_2X^2 + b_1X + b_0X^0 + b_{-1}X^{-1}$ . Remark 1.3.3 enables us to describe S(A, B) by determinants as follows.

$$\operatorname{sres}_{1}(A,B) = \mid A,B \mid = \det \begin{pmatrix} a_{2} & A \\ & & \\ b_{2} & B \end{pmatrix}.$$

$$\operatorname{sres}_0(A,B) = \mid \Theta A, A, \Theta B, B \mid = \det \left( \begin{array}{cccc} \sigma a_2 & \delta a_2 + \sigma a_1 & \delta a_1 + \sigma a_0 & \Theta A \\ \\ 0 & a_2 & a_1 & A \\ \\ & & & \\ \\ \sigma b_2 & \delta b_2 + \sigma b_1 & \delta b_1 + \sigma b_0 & \Theta B \\ \\ & & & \\ 0 & b_2 & b_1 & B \end{array} \right).$$

$$\operatorname{sres}_{-1}(A, B) = |\Theta^2 A, \Theta A, A, \Theta^2 B, \Theta B, B|,$$

that is

If A and B are in  $\mathcal{R}[X]$ , then the coefficients of  $X^{-1}$  in the subresultants of A and B are all equal to zero because the last column of  $\mathrm{mat}(\Theta^{n-j-1}A,\ldots,A,\ \Theta^{m-j-1}B,\ldots,B)$  is composed of zero entries. If  $\sigma = 1$ ,  $\delta = 0$ , and  $A, B \in \mathcal{R}[X]$ , then Definition 1.3.4 defines the algebraic subresultants in [8, 9, 4]. If  $\sigma=1$  and  $\delta=D$ , as given in Example 1.2.4, then Definition 1.3.4 defines the differential subresultants in [5, 24].

Some elementary properties of subresultants are given in the next lemma.

**Lemma 1.3.5** If A and B are in  $\mathcal{R}[X] \oplus \mathcal{R}$  with respective degrees m and n, where  $m \geq n \geq 0$ , then

1. 
$$\operatorname{sres}_{j}(A, B) \in [A, B]$$
, where  $n - 1 \ge j \ge -1$ ;

2. 
$$\deg(\operatorname{sres}_{j}(A, B)) \leq j$$
, where  $n - 1 \geq j \geq -1$ ;

3. 
$$\operatorname{sres}_{n-1}(A, B) = (-1)^{m-n+1} \operatorname{prem}(A, B)$$
.

Proof The first assertion follows from Lemma 1.3.1. Since the matrix

$$mat(\Theta^{n-j-1}A,\ldots,A,\Theta^{m-j-1}B,\ldots,B)$$

has (m+n-2j) rows and (m+n-j+1) columns, the second assertion holds by Definition 1.3.2. Since  $\operatorname{sres}_{n-1}(A,B) = |A,\Theta^{m-n}B,\ldots,B|$ , the pseudo-remainder formula (1.6) and lemma 1.3.2 imply that

$$lc(B)^{[m-n+1]}sres_{n-1}(A, B) = | prem(A, B), B^{[k]}, ..., B | ...$$

Moving prem(A, B) to the last row of the above determinant, we get

$$lc(B)^{[m-n+1]}sres_{n-1}(A,B) = (-1)^{m-n+1} | B^{[m-n]}, \dots, B, prem(A,B) |$$
.

Therefore, 
$$\operatorname{sres}_{n-1}(A, B) = (-1)^{m-n+1}\operatorname{prem}(A, B)$$
 by Lemma 1.3.4.

#### 1.3.3 Row Reduction on Subresultants

Some proofs in the algebraic subresultant theory are based on the fact that, if A and B are two univariate commutative polynomials in the indeterminate x, then

$$x \operatorname{prem}(A, B) = \operatorname{prem}(xA, xB).$$

However, the Ore operator  $\Theta$  and pseudo-division for Ore polynomials do not commute, that is, if A and B are two Ore polynomials, then in general

$$\Theta(\operatorname{prem}(A, B)) \neq \operatorname{prem}(\Theta A, \Theta B).$$

The following lemma describes the relation between  $\Theta(\operatorname{prem}(A, B))$  and  $\operatorname{prem}(\Theta A, \Theta B)$ .

**Lemma 1.3.6** Let A and B be in  $\mathcal{R}[X] \oplus \mathcal{R}$ , with respective degrees m and n, where  $m \geq n \geq 0$ . If C = prem(A, B) and  $C_k = \text{prem}(\Theta^k A, \Theta^k B)$ , for  $k \in \mathbb{N}^+$ , then  $C_k - \Theta^k C$  is an  $\mathcal{R}$ -linear combination of  $\Theta^{k-1}A, \ldots, A, \Theta^{m-n+k-1}B, \ldots, B$ .

**Proof** By the pseudo-remainder formula (1.6), we write

$$lc(B)^{[m-n+1]}A = \sum_{i=0}^{m-n} r_i \Theta^i B + C,$$
(1.11)

and

$$\left(\sigma^k \operatorname{lc}(B)\right)^{[m-n+1]} \Theta^k A = \sum_{i=0}^{m-n} s_i \Theta^{k+i} B + C_k, \tag{1.12}$$

where each of the  $r_i$ 's and  $s_i$ 's belongs to  $\mathcal{R}$ . Applying  $\Theta$  to equation (1.11) k times and using the extended Leibniz rule (Lemma 1.2.4), we obtain

$$\left(\sigma^{k} lc(B)\right)^{[m-n+1]} \Theta^{k} A + \sum_{j=0}^{k-1} q_{j} \Theta^{j} A = \sum_{i=0}^{m-n+k} h_{i} \Theta^{i} B + \Theta^{k} C, \tag{1.13}$$

where each of the  $q_j$ 's and  $h_i$ 's belongs to  $\mathcal{R}$ . Equations (1.12) and (1.13) imply that

$$\sum_{j=0}^{k-1} q_j \Theta^j A = \sum_{i=0}^{m-n} (h_{m+i} - s_i) \Theta^{k+i} B + \sum_{l=0}^{k-1} h_l \Theta^l B + \Theta^k C - C_k.$$

Since  $\Theta^{m-n+k}B$  is the only polynomial of degree (k+m) in the above equality,  $h_{m+k}-s_k=0$ . Hence,  $\Theta^kC-C_k$  is an  $\mathcal{R}$ -linear combination of  $\Theta^{k-1}A$ , ... A,  $\Theta^{k+m-n-1}B$ , ..., B.

We are ready to present the row-reduction formula for subresultants, by which the techniques for proving the algebraic subresultant theorem can be extended to Ore polynomials.

**Theorem 1.3.7** Let A and B be in  $\mathcal{R}[X] \oplus \mathcal{R}$ , with respective degrees m and n, where  $m \geq n \geq 0$ . If there exist non-zero  $u, v, w \in \mathcal{R}$  and  $F, G \in \mathcal{R}[X] \oplus \mathcal{R}$  such that uB = vF and  $\operatorname{sres}_{n-1}(A, B) = wG$ , then

$$u^{[m-i]} \operatorname{lc}(B)^{[m-n+1][n-i]} \operatorname{sres}_{i}(A, B) =$$

$$v^{[m-i]} w^{[n-i]} \mid \Theta^{m-i-1} F, \dots, F, \Theta^{n-i-1} G, \dots, G \mid,$$
(1.14)

for  $i = n - 1, n - 2, \ldots, -1$ .

**Proof** Let  $C = \operatorname{prem}(A, B)$ ,  $C_k = \operatorname{prem}(\Theta^k A, \Theta^k B)$ , for  $k \in \mathbb{N}$ , and  $S_i = \operatorname{sres}_i(A, B)$ , for  $i = n - 1, n - 2, \ldots, -1$ . Note that  $S_i = |\Theta^{n-i-1} A, \ldots, \Theta A, A, \Theta^{m-i-1} B, \ldots, \Theta B, B|$  by Definition 1.3.4. The pseudo-remainder formula for  $\Theta^{n-i-1} A$  and  $\Theta^{n-i-1} B$  implies that

$$\sigma^{n-i-1}(\mathrm{lc}(B))^{[m-n+1]}\Theta^{n-i-1}A - C_{n-i-1}$$

is an  $\mathcal{R}$ -linear combination of  $\Theta^{m-i-1}B, \ldots, \Theta^{n-i}B, \Theta^{n-i-1}B$ . Therefore,

$$\sigma^{n-i-1}(\mathrm{lc}(B))^{[m-n+1]}\Theta^{n-i-1}A - \Theta^{n-i-1}C$$

is an  $\mathcal{R}$ -linear combination of  $\Theta^{n-i-2}A$ , ...,  $\Theta A$ , A,  $\Theta^{m-i-1}B$ , ...,  $\Theta B$ , B by Lemma 1.3.6. It then follows from Lemma 1.3.2 that

$$\sigma^{n-i-1}(\mathrm{lc}(B))^{[m-n+1]}S_i = |\Theta^{n-i-1}C, \Theta^{n-i-2}A, \dots, A, \Theta^{m-i-1}B, \dots, B|.$$
 (1.15)

In the same way, we replace  $\Theta^j A$  by  $\Theta^j C$  on the right-hand side of equation (1.15), while, simultaneously, we multiply the power  $\sigma^j(\operatorname{lc}(B))^{[m-n+1]}$  on the left-hand side of the same equation, for  $j=n-i-2,\,n-i-3,\,\ldots,\,0$ . We eventually arrive at

$$lc(B)^{[n-i][m-n+1]}S_i = |\Theta^{n-i-1}C, \Theta^{n-i-2}C, \dots, C, \Theta^{m-i-1}B, \dots, B|.$$

Then, by the third assertion of Lemma 1.3.5,

$$lc(B)^{[n-i][m-n+1]}S_i = |\Theta^{m-i-1}B, \dots, B, \Theta^{n-i-1}S_{n-1}, \dots, S_{n-1}|.$$

This theorem thus follows from Lemma 1.3.3.

## 1.4 Subresultant Theorem and Algorithm

**Notation** To avoid endlessly repeating the same assumptions, in this section we let A and B be in  $\mathcal{R}[X] \oplus \mathcal{R}$ , with respective degrees m and n, where  $m \geq n \geq 0$ . Let  $S_n$  be B and  $S_j$  be  $\mathrm{sres}_j(A, B)$ , for  $j = n - 1, n - 2, \ldots, -1$ . The subresultant sequence S(A, B) consists of  $A, S_n, \ldots, S_0, S_{-1}$ .

This section has two parts. First, we prove the subresultant theorem and describe the gap structure of a subresultant sequence. Second, we present the subresultant algorithm.

#### 1.4.1 Subresultant Theorem

**Definition 1.4.1** The jth subresultant  $S_j$  is regular if  $S_j$  is of degree j, otherwise  $S_j$  is defective. In particular, the nth subresultant  $S_n$  is always regular.

First, we demonstrate the relation between the members of S(A, B) and subresultants of two consecutive non-zero members of S(A, B) in the next lemma. The subresultant theorem is one of its consequences. The proof given below is based on somewhat tedious calculations because of the presence of  $\sigma$ -factorial expressions.

#### Lemma 1.4.1 Let

$$\alpha_i = \operatorname{lc}(S_i), \quad (n \ge i \ge -1), \quad \beta_n = \sigma \operatorname{lc}(S_n)^{[m-n]}, \quad \text{and} \quad \beta_i = \sigma \operatorname{lc}(S_i), \quad (n-1 \ge i \ge -1).$$

If  $S_{j+1}$  is regular and  $S_j$  has degree r, for some j such that  $n-1 \ge j \ge 0$ , then the following hold:

1. If 
$$r \leq -1$$
, then

$$S_i = 0 \quad (j - 1 \ge i \ge -1).$$
 (1.16)

2. If  $r \geq 0$ , then

$$S_i = 0 \quad (j-1 \ge i \ge r+1),$$
 (1.17)

$$\beta_{j+1}^{[j-r]} S_r = \beta_j^{[j-r]} S_j, \tag{1.18}$$

and

$$\alpha_{j+1}^{[r-i]}\beta_{j+1}^{[j-i]}S_i = \operatorname{sres}_i(S_{j+1}, S_j) \quad (r-1 \ge i \ge -1).$$
(1.19)

**Proof** We proceed by induction on the sequence of the regular subresultants in S(A,B). As  $S_n$  is the first regular subresultant in S(A,B), we start with the case j=n-1. Let i be an integer such that  $n-2 \ge i \ge -1$ . By Definition 1.3.4 we have  $S_i = |\Theta^{n-1-i}A, \ldots, A, \Theta^{m-1-i}S_n, \ldots, S_n|$ . It follows from the row-reduction formula (1.14) that

$$\alpha_n^{[m-n+1][n-i]} S_i = R_i, \tag{1.20}$$

where  $R_i = |\Theta^{m-1-i}S_n, \dots, S_n, \Theta^{n-1-i}S_{n-1}, \dots, \Theta S_{n-1}, S_{n-1}|$ .

If  $S_{n-1}$  has degree less than 0, then  $\Theta S_{n-1}$  and  $S_{n-1}$  are  $\mathcal{R}$ -linearly dependent, so  $R_i = 0$ , and hence  $S_i = 0$  by (1.20), for  $i = n - 2, n - 3, \ldots, -1$ .

Assume that  $r \ge 0$ . If  $n-2 \ge i \ge r+1$ , then  $\deg S_n > 1 + \deg \Theta^{n-1-i} S_{n-1}$ . Thus,  $R_i = 0$  by Lemma 1.3.4, consequently,  $S_i = 0$  by (1.20).

If i=r, then  $R_r=\alpha_n^{[m-r]}\beta_{n-1}^{[n-1-r]}S_{n-1}$  by the second assertion of Lemma 1.3.4. Hence equation (1.20) can be rewritten as

$$\alpha_n^{[m-n+1][n-r]} S_r = \alpha_n^{[m-r]} \beta_{n-1}^{[n-1-r]} S_{n-1}. \tag{1.21}$$

As

$$\alpha_n^{[m-n+1][n-r]} = \alpha_n^{[m-r]} (\sigma \alpha_n)^{[m-n][n-1-r]}$$
 (by (4) in Lemma 1.2.5)  
=  $\alpha_n^{[m-r]} \beta_n^{[n-r-1]}$ ,

the equation  $\beta_n^{[n-1-r]} S_r = \beta_{n-1}^{[n-1-r]} S_{n-1}$  holds by (1.21).

If  $r-1 \ge i \ge -1$ , then  $R_i = (\sigma^{r-i}\alpha_n)^{[m-r]} \operatorname{sres}_i(S_n, S_{n-1})$  by the first assertion of Lemma 1.3.4. This equation and (1.20) imply that

$$\alpha_n^{[m-n+1][n-i]} S_i = (\sigma^{r-i} \alpha_n)^{[m-r]} \operatorname{sres}_i(S_n, S_{n-1}). \tag{1.22}$$

As

$$\begin{array}{lll} \alpha_n^{[m-n+1][n-i]} & = & \alpha_n^{[m-i]}\beta_n^{[n-1-i]} & (\mbox{by } (4) \mbox{ in Lemma } 1.2.5) \\ \\ & = & \alpha_n^{[r-i]}(\sigma^{r-i}\alpha_n)^{[m-r]}\beta_n^{[n-1-i]} & (\mbox{by } (2) \mbox{ in Lemma } 1.2.5), \end{array}$$

the equation  $\alpha_n^{[r-i]}\beta_n^{[n-1-i]}S_i=\operatorname{sres}_i(S_n,S_{n-1})$  holds by (1.22). The proof of the base case is done. We assume that the lemma holds for the regular subresultant  $S_{j+1}$ , and that  $\deg S_j=r$ , i.e., equations (1.16), (1.17), (1.18), and (1.19) hold. If  $r\leq -1$ , there is no non-zero subresultant following  $S_j$ , so there is nothing to prove. Suppose that  $r\geq 0$ . Then the regular subresultant next to  $S_{j+1}$  must be  $S_r$  by the induction hypothesis. Let  $\deg(S_{r-1})=t$ . We have to prove that, if  $t\leq -1$ , then

$$S_i = 0 \quad (r - 2 \ge i \ge -1);$$
 (1.23)

and that, if  $t \geq 0$ , then

$$S_i = 0 \quad (r - 2 \ge i \ge t + 1),$$
 (1.24)

$$\beta_r^{[r-1-t]} S_t = \beta_{r-1}^{[r-1-t]} S_{r-1}, \tag{1.25}$$

and

$$\alpha_r^{[t-i]} \beta_r^{[r-1-i]} S_i = \operatorname{sres}_i(S_r, S_{r-1}) \quad (t-1 \ge i \ge -1).$$
 (1.26)

Before going to induction, we point out two important relations hiding in (1.18). Equating the leading coefficients of both sides of (1.18) yields

$$\beta_{j+1}^{[j-r]}\alpha_r = \beta_j^{[j-r]}\alpha_j. \tag{1.27}$$

Applying  $\sigma$  to both sides of (1.27) yields

$$(\sigma \beta_{j+1})^{[j-r]} \beta_r = \beta_j^{[j-r+1]}. \tag{1.28}$$

We claim that

$$\alpha_r^{[j-i+1]}\beta_r^{[r-i-1]}S_i = T_i, \quad (r-2 \ge i \ge -1),$$
 (1.29)

where  $T_i = |\Theta^{j-i}S_r, ..., S_r, \Theta^{r-i-1}S_{r-1}, ..., \Theta S_{r-1}, S_{r-1}|$ .

Proof of the Claim. Equations (1.18) and (1.19) (setting i = r - 1) give us

$$\beta_j^{[j-r]} S_j = \beta_{j+1}^{[j-r]} S_r$$
 and  $\operatorname{sres}_{r-1}(S_{j+1}, S_j) = \left(\alpha_{j+1} \beta_{j+1}^{[j-r+1]}\right) S_{r-1}.$  (1.30)

Using the relations given in (1.30) and row-reduction formula (1.14), we derive from (1.19) that

$$\left(\beta_{j}^{[j-r][j-i+1]}\right)\left(\alpha_{j}^{[j-r+2][r-i]}\right)\left(\alpha_{j+1}^{[r-i]}\beta_{j+1}^{[j-i]}S_{i}\right) = \left(\beta_{j+1}^{[j-r][j-i+1]}\right)\left(\alpha_{j+1}^{[r-i]}\beta_{j+1}^{[j-r+1][r-i]}\right)T_{i}.$$

Let

$$r_i = \frac{\left(\beta_j^{[j-r][j-i+1]} \alpha_j^{[j-r+2][r-i]}\right) \left(\alpha_{j+1}^{[r-i]} \beta_{j+1}^{[j-i]}\right)}{\beta_{j+1}^{[j-r][j-i+1]} \left(\alpha_{j+1}^{[r-i]} \beta_{j+1}^{[j-r+1][r-i]}\right)}.$$

Then  $r_i S_i = T_i$ . Our claim will be proved if we show  $r_i = \alpha_r^{[j-i+1]} \beta_r^{[r-i-1]}$ . Canceling  $\alpha_{j+1}^{[r-i]}$  yields

$$r_i = \left(\frac{\beta_j^{[j-r][j-i+1]}}{\beta_{j+1}^{[j-r][j-i+1]}}\right) \frac{\alpha_j^{[j-r+2][r-i]}\beta_{j+1}^{[j-i]}}{\beta_{j+1}^{[j-r+1][r-i]}}.$$

The above equality can be simplified by (1.27) to

$$r_{i} = \left(\frac{\alpha_{r}^{[j-i+1]}}{\alpha_{j}^{[j-i+1]}}\right) \frac{\alpha_{j}^{[j-r+2][r-i]} \beta_{j+1}^{[j-i]}}{\beta_{j+1}^{[j-r+1][r-i]}}.$$
(1.31)

The fourth equality in Lemma 1.2.5 implies that

$$\alpha_j^{[j-r+2][r-i]} = \alpha_j^{[j-i+1]} \beta_j^{[j-r+1][r-i-1]} \quad \text{and} \quad \beta_{j+1}^{[j-r+1][r-i]} = \beta_{j+1}^{[j-i]} (\sigma \beta_{j+1})^{[j-r][r-i-1]}.$$

So equation (1.31) can be further simplified to

$$r_i = \alpha_r^{[j-i+1]} \left( \frac{\beta_j^{[j-r+1][r-i-1]}}{(\sigma \beta_{j+1})^{[j-r][r-i-1]}} \right).$$

It then follows from (1.28) that  $r_i = \alpha_r^{[j-i+1]} \beta_r^{[r-i-1]}$ . The claim is proved.

If  $t \leq -1$ , then  $T_i = 0$ , for  $r - 2 \geq i \geq -1$ , because  $\Theta S_{r-1}$  and  $\Theta S_{r-1}$  are  $\mathcal{R}$ -linearly dependent, so  $S_i = 0$  by (1.29), for  $i = r - 2, r - 3, \ldots, -1$ .

Assume that  $t \geq 0$ . If  $r - 2 \geq i \geq t + 1$ , then  $T_i = 0$  since  $\deg(S_r) > 1 + \deg(\Theta^{r-i-1}S_{r-1})$ . Hence  $S_i = 0$  by (1.29).

If i = t, then  $T_i = \alpha_r^{[j-t+1]} \beta_{r-1}^{[r-t-1]} S_{r-1}$  by Lemma 1.3.4. Equation (1.25) holds by (1.29).

If  $t-1 \ge i \ge -1$ , then  $T_i = (\sigma^{t-i}\alpha_r)^{[j-t+1]} \operatorname{sres}_i(S_r, S_{r-1})$  by Lemma 1.3.4, and hence (1.29) implies that

$$\alpha_r^{[j-i+1]} \beta_r^{[r-i-1]} S_i = (\sigma^{t-i} \alpha_r)^{[j-t+1]} \operatorname{sres}_i(S_r, S_{r-1}). \tag{1.32}$$

It follows from the second assertion of Lemma 1.2.5 that

$$\alpha_r^{[j-i+1]} = \alpha_r^{[(t-i)+(j-t+1)]} = \alpha_r^{[t-i]} (\sigma^{t-i}\alpha_r)^{[j-t+1]}.$$

Using this relation to remove the like  $\sigma$ -factorials from both sides of (1.32), we get (1.26).

Theorem 1.4.2 (Subresultant Theorem) Let

$$\alpha_i = \operatorname{lc}(S_i) \quad (n \ge i \ge -1), \quad \beta_n = \sigma \operatorname{lc}(S_n)^{[m-n]}, \quad \text{and} \quad \beta_i = \sigma \operatorname{lc}(S_i) \quad (n-1 \ge i \ge -1).$$

If  $S_{j+1}$  is regular and  $S_j$  has degree r, for some j with  $n-1 \geq j \geq 0$ , then the following hold:

1. If r < -1, then

$$S_i = 0, \quad (j - 1 \ge i \ge -1).$$
 (1.33)

2. If  $r \geq 0$ , then

$$S_i = 0, \quad (j - 1 \ge i \ge r + 1),$$
 (1.34)

$$\beta_{j+1}^{[j-r]} S_r = \beta_j^{[j-r]} S_j, \tag{1.35}$$

and

$$\alpha_{j+1}\beta_{j+1}^{[j-r+1]}S_{r-1} = (-1)^{j-r}\operatorname{prem}(S_{j+1}, S_j).$$
 (1.36)

**Proof** Equations (1.33), (1.34), and (1.35) hold by Lemma 1.4.1. Set i = r - 1. Then equation (1.19) in Lemma 1.4.1 becomes  $\alpha_{j+1}\beta_{j+1}^{[j-r+1]}S_{r-1} = \operatorname{sres}_{r-1}(S_n, S_{n-1})$ . Hence, equation (1.36) holds by the third assertion of Lemma 1.3.5.

If  $\sigma = 1$  and  $\delta = 0$ , and  $A, B \in \mathcal{R}[X]$ , then Theorem 1.4.2 becomes the algebraic subresultant theorem in [26]. If  $\sigma = 1$  and  $\delta = D$ , as given in Example 1.2.4, then Theorem 1.4.2 becomes the differential subresultant theorem in [24].

The next corollary is a formula-free version of the subresultant theorem.

Corollary 1.4.3 Let  $\deg S_{j+1}=j+1$  and  $\deg S_j=r$ , for some j such that  $n-1\geq j\geq 0$ . If  $r\leq -1$ , then  $S_i=0$ , for  $i=j-1,\,j-2,\,\ldots,\,-1$ . If r>-1, then  $S_i=0$ , for  $i=j-1,\,j-2,\,\ldots,\,r+1,\,S_j\sim_{\mathcal{R}} S_r$ , and  $S_{r-1}\sim_{\mathcal{R}} \operatorname{prem}(S_{j+1},S_j)$ .

**Definition 1.4.2** A defective subresultant is said to be *isolated* if it is of degree -1.

Remark 1.4.3 S(A, B) does not contain any isolated subresultant if A and B belong to R[X].

Now, we extend subresultant sequences of the first and second kinds in [37]. We prove that subresultant sequences of the first kind are PRS's in the next section.

**Definition 1.4.4** The subresultant sequence of A and B of the first kind is the subsequence of S(A, B) that consists of the following polynomials:

- 1. A, B, and
- 2.  $S_j$ , if  $S_{j+1}$  is regular and  $S_j$  is nonzero.

The subresultant sequence of A and B of the second kind is the subsequence of S(A, B) that consists of A, B and other regular subresultants of S(A, B). The subresultant sequences of A and B of the first and second kinds are denoted by  $S_1(A, B)$  and  $S_2(A, B)$ , respectively.

The next corollary describes the relation between  $S_1(A, B)$  and  $S_2(A, B)$ .

Corollary 1.4.4 Let  $S_2(A,B)$  consist of  $A, S_n, S_{j_3}, S_{j_4}, \dots, S_{j_{l-1}}, S_{j_l}$ . If S(A,B) does not contain any isolated subresultant, then  $S_1(A,B)$  consists of  $A, S_n, S_{n-1}, S_{j_3-1}, S_{j_4-1}, \dots, S_{j_{l-1}-1}$ . Otherwise,  $S_1(A,B)$  consists of  $A, S_n, S_{n-1}, S_{j_3-1}, S_{j_4-1}, \dots, S_{j_{l-1}-1}, S_{j_l-1}$ . In any case we have  $S_{n-1} \sim_{\mathcal{R}} S_{j_3}$  and  $S_{j_i-1} \sim_{\mathcal{R}} S_{j_{i+1}}$ , for  $i=3,4,\ldots,l-1$ .

**Proof** The sequence A,  $S_n$ ,  $S_{n-1}$ ,  $S_{j_3-1}$ ,  $S_{j_4-1}$ , ...,  $S_{j_{l-1}-1}$  is a subsequence of  $S_1(A,B)$  by Definition 1.4.4. If  $S_{j_l-1}$  is zero, then all the subresultants following  $S_{j_l}$  are zero by Corollary 1.4.3. If  $S_{j_l-1}$  is nonzero, then it must be isolated, otherwise there would be a regular subresultant following  $S_{j_l}$  by Corollary 1.4.3, which is a contradiction. Since  $S_n$  is regular,  $S_{n-1} \sim_{\mathcal{R}} S_{j_3}$  by Corollary 1.4.3. In the same way we deduce that  $S_{j_l-1} \sim_{\mathcal{R}} S_{j_{l+1}}$ , for  $i=3,4,\ldots,l-1$ .

If  $S_{j_{i+1}}$  and  $S_{j_i}$  are consecutive members in  $S_2(A, B)$ , then the  $S_i$ 's between  $S_{j_{i+1}-1}$  and  $S_{j_i}$  are all zero by Corollary 1.4.3. Hence, all the non-zero subresultants are contained in either  $S_2(A, B)$  or  $S_1(A, B)$ . Accordingly, all the defective subresultants are contained in  $S_1(A, B)$ . If there is no defective subresultant in S(A, B), then both  $S_1(A, B)$  and  $S_2(A, B)$  coincide with S(A, B).

Corollary 1.4.5 If there exists an isolated subresultant in S(A, B), then it is the last non-zero member in S(A, B).

**Proof** If  $S_j$  is isolated, then  $S_j$  is contained in  $S_1(A, B)$ , and  $S_{j+1}$  is regular. Hence, all the subresultants following  $S_j$  are equal to zero by Corollary 1.4.3.

The gap structure of S(A, B) is given in Figure 1.1.

Note that the gap-structure of the subresultant sequence of two Ore polynomials is slightly more complicated than that of an algebraic subresultant sequence due to the possible presence of isolated subresultants.

In summary, the subresultant theorem and its corollaries reveal the following:

• If  $S_i$  and  $S_j$  (i > j) are both nonzero and of the same degree, then  $S_i$  and  $S_j$  are two consecutive non-zero subresultants in S(A, B),  $S_i$  is defective,  $S_j$  is regular, and  $S_i \sim_{\mathcal{R}} S_j$ .

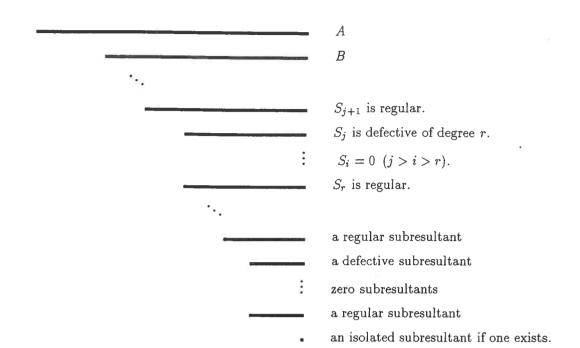

Figure 1.1: The gap structure of S(A, B)

- If  $S_i$  and  $S_j$  (i > j) are two consecutive non-zero subresultants with distinct degrees, then i = j + 1,  $S_i$  is regular, and prem $(S_i, S_j) \sim_{\mathcal{R}} S_{r-1}$ , where  $r = \deg S_j$ .
- The coefficients of similarity mentioned above are given explicitly by (1.35) and (1.36) in the subresultant theorem.

#### 1.4.2 Subresultant Algorithm

Throughout this section  $\mathcal{S}_1(A,B)$  and  $\mathcal{S}_2(A,B)$  are

$$A_1, A_2, A_3, \dots, A_{k_1}, \text{ and, } B_1, B_2, B_3, \dots, B_{k_2},$$

respectively, where  $A_1 = B_1 = A$  and  $A_2 = B_2 = B$ . By Corollary 1.4.4,  $k_1 = k_2$  if there is no isolated subresultant in S(A, B), otherwise  $k_1 = k_2 + 1$ .

**Lemma 1.4.6** Let  $b_2 = lc(B)^{[m-n]}$ ,  $a_i = lc(A_i)$ ,  $b_i = lc(B_i)$ , and  $l_i = deg A_{i-1} - deg A_i + 1$ , for  $i = 3, \ldots, k_2$ . Then

$$(\sigma a_i)^{[l_i-2]} A_i = (\sigma b_{i-1})^{[l_i-2]} B_i. \tag{1.37}$$

In particular,  $a_i^{[l_i-1]} = (\sigma b_{i-1})^{[l_i-2]} b_i$ .

**Proof** Let  $B_{i-1} = S_{j+1}$ . Then  $A_i = S_j$  by Corollary 1.4.4. Let  $\deg A_i = r$ . Then  $B_i = S_r$  by Corollary 1.4.3. Since  $\deg A_{i-1} = \deg B_{i-1} = j+1$  by Corollary 1.4.4, we get  $l_i = j-r+2$ . Hence equation (1.37) holds by (1.35) in the subresultant theorem. Equating the leading coefficients of both sides of (1.37) yields  $a_i^{[l_i-1]} = (\sigma b_{i-1})^{[l_i-2]}b_i$ .

The subresultant algorithm given in the next theorem generalizes the algebraic subresultant algorithm by Brown and Traub [4]. This algorithm computes  $S_1(A, B)$  without expanding determinants directly, and proceeds as the Euclidean algorithm but removes a factor from the coefficients in the pseudo-remainder after each pseudo-division. A byproduct of this algorithm is the sequence of the leading coefficients of the members of  $S_2(A, B)$ . Consequently, we can use Lemma 1.4.6 to construct S(A, B) from the output of the subresultant algorithm.

Theorem 1.4.7 (Subresultant Algorithm) Let

$$a_1 = b_1 = 1$$
,  $a_2 = lc(A_2)$ , and  $b_2 = lc(B_2)^{[m-n]}$ ,

and let

$$a_i = \operatorname{lc}(A_i), \quad b_i = \operatorname{lc}(B_i), \quad and \quad l_i = \operatorname{deg} A_{i-1} - \operatorname{deg} A_i + 1,$$

for  $i = 3, \ldots, \min(k_1, k_2)$ . Then

$$A_i = \operatorname{prem}(A_{i-2}, A_{i-1})/e_i, \tag{1.38}$$

where

$$e_i = (-1)^{l_{i-1}} (\sigma b_{i-2})^{[l_{i-1}-1]} a_{i-2}, \tag{1.39}$$

for  $i = 3, 4, ..., k_1$ . In particular,  $S_1(A, B)$  is a PRS of A and B.

**Proof** We handle the cases in which i = 3 or 4, and then consider the general case.

If i=3, then  $e_3=(-1)^{m-n+1}$ , so  $\operatorname{prem}(A_1,A_2)=(-1)^{m-n+1}S_{n-1}=e_3A_3$  by the third assertion of Lemma 1.3.5. Note that, if  $\deg S_{n-1}\leq -1$ , then  $k_1\leq 3$  by Corollary 1.4.3. To proceed, we assume that  $\deg A_3=r\geq 0$ . If i=4, then

$$e_4 = (-1)^{n-r+1} a_2(\sigma b_2)^{[l_3-1]} = \operatorname{lc}(B) \sigma(\operatorname{lc}(B))^{[m-n][n-r]}.$$

Equation (1.36) in the subresultant theorem (setting j = n-1) implies that  $e_4S_{r-1} = \text{prem}(A_2, A_3)$ . If  $S_{r-1}$  is nonzero, then  $A_4 = S_{r-1}$  since  $S_r$  is regular. Let  $5 \le i \le k_1$ . By (1.37) in Lemma 1.4.6, we have  $(\sigma a_{i-2})^{[l_{i-2}-2]}A_{i-2} = (\sigma b_{i-3})^{[l_{i-2}-2]}B_{i-2}$ . Therefore,  $\operatorname{prem}((\sigma a_{i-2})^{[l_{i-2}-2]}A_{i-2}, A_{i-1}) = \operatorname{prem}((\sigma b_{i-3})^{[l_{i-2}-2]}B_{i-2}, A_{i-1})$ . From this equation we derive

$$(\sigma a_{i-2})^{[l_{i-2}-2]}\operatorname{prem}(A_{i-2}, A_{i-1}) = (\sigma b_{i-3})^{[l_{i-2}-2]}\operatorname{prem}(B_{i-2}, A_{i-1}). \tag{1.40}$$

Let  $B_{i-2} = S_{j+1}$ . Then  $A_{i-1} = S_j$  by Corollary 1.4.4. Assume that  $\deg A_{i-1} = r$ . Then  $B_{i-1} = S_r$  and  $A_i = S_{r-1}$  by the same corollary. We deduce that

$$\operatorname{prem}(B_{i-2}, A_{i-1}) = \operatorname{prem}(S_{j+1}, S_j) = (-b_{i-2})^{[l_{i-1}]} A_i, \tag{1.41}$$

where the last equality follows from (1.36) in the subresultant theorem, since  $lc(S_{j+1}) = b_{i-2}$  and  $l_{i-1} = j - r + 2$ . Equations (1.40) and (1.41) imply that

$$(\sigma a_{i-2})^{[l_{i-2}-2]}\operatorname{prem}(A_{i-2},A_{i-1}) = (-b_{i-2})^{[l_{i-1}]}(\sigma b_{i-3})^{[l_{i-2}-2]}A_i.$$

Multiplying  $a_{i-2}$  to both sides of the above equation yields

$$a_{i-2}^{[l_{i-2}-1]}\mathrm{prem}(A_{i-2},A_{i-1}) = a_{i-2}(-b_{i-2})^{[l_{i+1}]}(\sigma b_{i-3})^{[l_{i-2}-2]}A_{i}.$$

Simplifying the  $\sigma$ -factorials of the above equality by Lemma 1.4.6, we see that

$$b_{i-2}\operatorname{prem}(A_{i-2}, A_{i-1}) = (-1)^{l_{i-1}}a_{i-2}b_{i-2}^{[l_{i-1}]}A_i.$$

Equation (1.38) follows.

It remains to prove that  $\deg(A_{k_1}) = -1$  or  $\operatorname{prem}(A_{k_1-1}, A_{k_1}) = 0$ . Assume that  $\deg A_{k_1} = r \geq 0$  and that  $A_{k_1} = S_j$ . Then  $B_{k_1-1} = S_{j+1}$  by Corollary 1.4.4. It follows that  $\operatorname{prem}(A_{k_1-1}, A_{k_1})$  and  $\operatorname{prem}(S_{j+1}, S_j)$  are similar over  $\mathcal{R}$ . Note that  $\operatorname{prem}(S_{j+1}, S_j) = 0$ , otherwise  $S_{r-1}$  would be nonzero, so  $S_{r-1}$  is in  $S_1(A, B)$ , contradicting the fact that  $S_j$  is the last member of  $S_1(A, B)$ . Consequently,  $\operatorname{prem}(A_{k_1-1}, A_{k_1}) = 0$ .

**Remark 1.4.5** Using (1.38) in Theorem 1.4.7, we may get  $A_i$  by computing prem $(A_{i-2}, A_{i-1})$  and removing the extraneous factor  $e_i$  from the pseudo-remainder, where  $e_i$  is computed by equation (1.39). At first glance, one might think that one needs both the  $a_i$ 's and the  $b_i$ 's to compute the  $e_i$ 's. However, the recursive formula  $b_i = a_i^{[l_i-1]}/(\sigma b_{i-1})^{[l_i-2]}$  in Lemma 1.4.6 enables us to compute the  $b_i$ 's by the  $a_i$ 's.

# Chapter 2

# Applications of the Subresultant Theory

We will apply the subresultant theory developed in Chapter 1 to three fundamental problems, namely, deciding  $\Theta$ -compatibility, computing GCRDs, and computing LCLMs. Using the subresultant theorem we present a characterization of the  $\Theta$ -compatibility of two elements in an Ore polynomial module, define the Sylvester resultant, derive determinant formulas for GCRDs and LCLMs, and estimate multiplicative bounds for the denominators of the monic GCRD and LCLM of two elements in an Ore polynomial ring. Propositions 2.2.3 and 2.2.4 in this chapter establish the basis for the modular algorithm for computing GCRDs over  $\mathbf{Z}[t]$  in Chapter 3.

The subresultant algorithm described in Chapter 1 may also be applied to various back-and-forth division processes in linear differential and difference algebra, for example, computing the characteristic sets for a linear differential ideal [21, pp. 150-155], and reducing a system of linear homogeneous equations to a diagonal form [35, pp. 39-41]. But we will not study Ore polynomials of special kinds in this thesis.

Throughout this chapter  $(\mathcal{R}[X] \oplus \mathcal{R}, \Theta, \sigma, \delta)$  is an Ore polynomial module. For brevity we denote this module by  $\mathcal{R}[X] \oplus \mathcal{R}$ . We fix A and B in  $\mathcal{R}[X] \oplus \mathcal{R}$  with respective degrees m and n, where  $m \geq n \geq 0$ .

The organization of this chapter is as follows. In Section 2.1, we present two methods for deciding the  $\Theta$ -compatibility of two elements in  $\mathcal{R}[X] \oplus \mathcal{R}$  and define the Sylvester resultant of two elements in  $\mathcal{R}[X]$ . Section 2.2 is devoted to studying the relation between GCRDs and subresultants. We apply the subresultant theory to the computation of LCLMs in Section 2.3.

# 2.1 Deciding ⊖-Compatibility by Subresultants

Two methods are presented for deciding  $\Theta$ -compatibility by subresultants. If  $\mathcal{R}[X] \oplus \mathcal{R}$  is the module of linear differential polynomials, the two methods may be seen as the improvements of the differential Euclidean algorithm [35] and differential resultants [1], respectively.

# Theorem 2.1.1 The following statements are equivalent:

- 1. A and B are  $\Theta$ -compatible.
- 2.  $\operatorname{sres}_{-1}(A, B)$  is equal to zero and the last non-zero member of  $\mathcal{S}(A, B)$  is regular.
- 3. The last member in  $S_1(A, B)$  is of degree greater than -1.

**Proof**  $(1 \Longrightarrow 2)$  Since  $\operatorname{sres}_{-1}(A, B)$  is in [A, B],  $\operatorname{sres}_{-1}(A, B)$  is equal to zero. If the last non-zero subresultant were defective, then it would be isolated by Corollary 1.4.4, which is a contradiction to the assumption that A and B are  $\Theta$ -compatible.

 $(2 \Longrightarrow 3)$  This is immediate from Corollary 1.4.4.

$$(3 \Longrightarrow 1)$$
 This follows from the fact that  $S_1(A, B)$  is a PRS (see, Theorem 1.4.7).

Observe that if  $\operatorname{sres}_k(A,B)$  is a member in  $\mathcal{S}_1(A,B)$ , with degree r, then the only candidate of the member next to  $\operatorname{sres}_k(A,B)$  in  $\mathcal{S}_1(A,B)$  is  $\operatorname{sres}_{r-1}(A,B)$  (see Corollary 1.4.3). Using this observation and the third equivalent condition of Theorem 2.1.1, we present the algorithm COMP\_t for deciding the  $\Theta$ -compatibility of A and B. COMP\_t proceeds by computing the degrees of the members in  $\mathcal{S}_1(A,B)$  in a top-down fashion.

#### algorithm COMP\_t

**Input:**  $A, B \in \mathcal{R}[X] \oplus \mathcal{R}$  with deg  $A \ge \deg B \ge 0$ .

Output: TRUE if A and B are  $\Theta$ -compatible. Otherwise, FALSE.

```
    r ← deg B;
    while true do {
    r ← deg sres<sub>r-1</sub>(A, B);
    if r = -∞ then return(TRUE);
    if r = -1 then return(FALSE); }
```

The second algorithm, named COMP\_b, for deciding the  $\Theta$ -compatibility is based on the second assertion of Theorem 2.1.1 and the fact that the last non-zero member in  $\mathcal{S}(A,B)$  is either regular or isolated. COMP\_b proceeds by computing the degrees of the members in  $\mathcal{S}(A,B)$  in a bottom-up fashion.

#### algorithm COMP\_b

Input:  $A, B \in \mathcal{R}[X] \oplus \mathcal{R}$  with deg  $A \ge \deg B \ge 0$ .

Output: TRUE if A and B are  $\Theta$ -compatible. Otherwise, FALSE.

- 1. If  $sres_{-1}(A, B) \neq 0$  then return(FALSE);
- 2.  $r \leftarrow \deg B$ ;
- 3. for i = 0 to r do {
- 4. if  $coeff(sres_i(A, B), X^i) \neq 0$  then return(TRUE);
- 5. if coeff(sres<sub>i</sub>(A, B),  $X^{-1}$ )  $\neq$  0 then return(FALSE); }

Remark 2.1.1 In COMP\_t and COMP\_b, we do not specifically describe how to compute the degree and coefficients of a subresultant, since the ground domain  $\mathcal{R}$  is merely a commutative domain. Of course, determinants can always be computed by minor expansion [16, §9.4]. The subresultant algorithm may be used in COMP\_t if exact division in  $\mathcal{R}$  is computable. Note that we need only decide whether some determinants are equal to zero in both COMP\_t and COMP\_b.

Next, we study the  $\Theta$ -compatibility of two Ore polynomials in  $\mathcal{R}[X]$ .

**Definition 2.1.2** For A and B in  $\mathcal{R}[X]$ , the subresultant  $sres_0(A, B)$  is called the (right) Sylvester resultant of A and B and denoted by res(A, B).

This definition extends the definitions of the (right) Sylvester-like resultants for two univariate algebraic polynomials, two linear differential operators [1, 5], and two linear shift operators [29].

**Theorem 2.1.2** For A and B in  $\mathcal{R}[X]$ , the left ideal [A, B] does not contain any element of degree 0 if and only if res(A, B) is equal to zero.

**Proof** If [A, B] does not contain any element of degree 0, then res(A, B) is equal to zero because  $deg(res(A, B)) \leq 0$  and  $res(A, B) \in [A, B]$ . Conversely, if res(A, B) is equal to zero, the last member of  $S_1(A, B)$  is of degree greater than 0. Thus, [A, B] does not contain any elements of degree 0 because  $S_1(A, B)$  is a PRS.

# 2.2 Greatest Common Right Divisors

Notation In the remainder of this chapter, A and B belong to the Ore polynomial ring R[X].

The goal of this section is to describe the relation between the GCRDs and subresultants of two Ore polynomials. In order to describe (right) divisibility, we feel it convenient to consider Ore polynomials with coefficients in a commutative field. For this purpose we extend  $\sigma$  and  $\delta$  to the quotient field of  $\mathcal{R}$ .

**Proposition 2.2.1** If  $\mathcal{F}$  is the quotient field of  $\mathcal{R}$ , then the conjugate operator  $\sigma$  and pseudo-derivation  $\delta$  can be uniquely extended to  $\mathcal{F}$  by letting

$$\sigma\left(\frac{a}{b}\right) = \frac{\sigma a}{\sigma b} \tag{2.1}$$

and

$$\delta\left(\frac{a}{b}\right) = \frac{b(\delta a) - a(\delta b)}{(\sigma b)b},\tag{2.2}$$

for  $a, b \in \mathcal{R}$  with  $b \neq 0$ .

Proof We have to verify the following:

- 1.  $\sigma$  is an injective endomorphism of the field  $\mathcal{F}$ .
- 2.  $\delta$  is an endomorphism of the additive group  $\mathcal{F}$ .
- 3. For all  $r, s \in \mathcal{F}$ ,  $\delta(rs) = \sigma(r)\delta(s) + \delta(r)s$ .

From the identity  $\delta(ab) = \delta(ba)$ , for  $a, b \in \mathcal{R}$ , and (1.2) in Proposition 1.2.1, it follows that

$$b(\delta a) - a(\delta b) = (\sigma b)(\delta a) - (\sigma a)(\delta b). \tag{2.3}$$

Let a/b=c/d, where  $a,b,c,d\in\mathcal{R}$  and  $bd\neq 0$ . Then  $\sigma(d)\sigma(a)=\sigma(c)\sigma(b)$  since  $\sigma$  is a ring homomorphism, hence,  $\sigma$  is well defined on  $\mathcal{F}$ . Applying  $\delta$  to the equality da=cb yields

$$(\sigma d)(\delta a) + (\delta d)a = (\sigma c)(\delta b) + (\delta c)b,$$

consequently,

$$(\sigma d)(\delta a) - (\sigma c)(\delta b) = (\delta c)b - (\delta d)a.$$

Multiplying both sides of the previous equality by  $(\sigma b)d$  yields

$$d((\sigma d)(\sigma b)(\delta a) - \sigma(bc)(\delta b)) = (\sigma b)(bd(\delta c) - (ad)(\delta d)),$$

which, together with the equation da = cb, implies that

$$d(\sigma d)((\sigma b)(\delta a) - (\sigma a)(\delta b)) = b(\sigma b)(d(\sigma c) - c(\delta d)).$$

It then follows from equation (2.3) that

$$\frac{b(\delta a) - a(\delta b)}{b(\sigma b)} = \frac{d(\sigma c) - c(\delta d)}{d(\sigma d)}.$$

Hence  $\delta$  is well defined on  $\mathcal{F}$ .

Clearly,  $\sigma$  is a ring endomorphism of  $\mathcal{F}$ . The distributivity of  $\delta$  with respect to addition is proved by the following calculation: for  $a,b,c,\in\mathcal{R}$  with  $b\neq 0$ ,

$$\delta\left(\frac{a}{b}+\frac{c}{b}\right)=\delta\left(\frac{a+c}{b}\right)=\frac{b\delta(a+c)-(a+c)\delta(b)}{(\sigma b)b}=\delta\left(\frac{a}{b}\right)+\delta\left(\frac{c}{b}\right).$$

It remains to verify the multiplicative rule, that is, for all  $a, b, c, d \in \mathcal{R}$ , with  $bd \neq 0$ ,

$$\delta\left(\frac{a}{b}\frac{c}{d}\right) = \sigma\left(\frac{a}{b}\right)\delta\left(\frac{c}{d}\right) + \delta\left(\frac{a}{b}\right)\left(\frac{c}{d}\right).$$

We calculate

$$bd\sigma(bd)\left(\sigma\left(\frac{a}{b}\right)\delta\left(\frac{c}{d}\right) + \left(\frac{c}{d}\right)\delta\left(\frac{a}{b}\right)\right) = \\ = b\sigma(a)(d\delta(c) - c\delta(d)) + c\sigma(d)(b\delta(a) - a\delta(b)) \\ = bd\sigma(a)\delta(c) - ac\sigma(d)\delta(b) - cb\sigma(a)\delta(d) + cb\sigma(d)\delta(a) \\ = bd(\sigma(a)\delta(c) + c\delta(a) - c\delta(a)) - ac(\sigma(d)\delta(b) + b\delta(d) - b\delta(d)) - cb\sigma(a)\delta(d) + cb\sigma(d)\delta(a) \\ = bd\delta(ac) - ac\delta(bd) + cb(\sigma(d) - d)\delta(a) - cb(\sigma(a) - a)\delta(d) \\ = bd\delta(ac) - ac\delta(bd) + cb(\sigma(d)\delta(a) - \sigma(a)\delta(d) - d\delta(a) + a\delta(d)) \\ = bd\delta(ac) - ac\delta(bd) \quad \text{(by equation (2.3))} \\ = bd\sigma(bd)\delta\left(\frac{a}{b}\frac{c}{d}\right).$$

The multiplicative rule holds.

If  $\sigma'$  is a conjugate operator extending  $\sigma$  and  $\delta'$  is a pseudo-derivation (with respect to  $\sigma'$ ) extending  $\delta$ , then, for every non-zero b in  $\mathcal{R}$ ,

$$\sigma'\left(b\frac{1}{b}\right) = \sigma(b)\sigma'\left(\frac{1}{b}\right) = 1,$$

so  $\sigma'(1/b)=1/\sigma(b).$  From the property that  $\delta(1)=0$  (see, Remark 1.2.2), we deduce

$$\delta'\left(b\frac{1}{b}\right) = \sigma(b)\delta'\left(\frac{1}{b}\right) + \frac{\delta(b)}{b} = 0.$$

Thus

$$\delta'\left(\frac{1}{b}\right) = -\frac{\delta(b)}{b\sigma(b)}.$$

The uniqueness then follows from the multiplicative rule of  $\sigma'$  and  $\delta'$ .

By Propositions 1.2.1 and 2.2.1, the Ore operator  $\Theta$  on  $\mathcal{R}[X]$  can be uniquely extended to  $\mathcal{F}[X]$ . In the rest of this chapter, the vector space  $\mathcal{F}[X]$  is regarded as an Ore polynomial ring whose Ore operator, conjugate operator, and pseudo-derivation are also denoted by  $\Theta$ ,  $\sigma$ , and  $\delta$ , respectively.

**Definition 2.2.1** A non-zero polynomial in  $\mathcal{F}[X]$  of highest degree, which divides both A and B on the right, is called a GCRD of A and B.

**Lemma 2.2.2** If  $G_1$  and  $G_2$  are two GCRDs of A and B, then  $G_1$  and  $G_2$  are similar over  $\mathcal{F}$ . If the sequence  $A, B, A_3, \ldots, A_k$  is a PRS, then  $A_k$  is a GCRD of A and B.

**Proof** See, Ore [33, p. 484].

**Example 2.2.2** Let D be the differential operator on  $\mathbf{Z}[t]$  that sends  $t^n$  to  $nt^{n-1}$ , for all  $n \in \mathbb{N}^+$ . Then  $(\mathbf{Z}[t][D], 1, D)$  is an Ore polynomial ring. One can easily verify that  $tD^3 = D^2(tD-2)$ . Thus, (tD-2) is a GCRD of  $D^3$  and (tD-2). Note that the product of two primitive polynomials is not necessarily primitive. Moreover, there does not exist A in  $\mathbf{Z}[t][X]$  such that  $D^3 = A(tD-2)$ .

**Example 2.2.3** Let E be the shift operator on  $\mathbf{Z}[t]$  that sends  $t^n$  to  $(t+1)^n$ , for all  $n \in \mathbb{N}^+$ . Then  $(\mathbf{Z}[t][E], E, \mathbf{0})$  is an Ore polynomial ring. If

$$A = t(t+1)E^2 - 2t(t+2)E + (t+1)(t+2)$$
 and  $B = (t-1)E^2 - (3t-2)E + 2t$ ,

then a GCRD of A and B is G = tE - (t+1). Note that the gcd(lc(A), lc(B)) = 1, but lc(G) = t.

Now, we describe the relation between the GCRDs and subresultants of two Ore polynomials.

**Proposition 2.2.3** If d is the degree of the GCRDs of A and B, then the dth subresultant of A and B is a GCRD of A and B.

**Proof** As A and B are in  $\mathcal{R}[X]$ ,  $\mathcal{S}_2(A, B)$  is a PRS of A and B by Corollary 1.4.4. If d is the degree of the GCRDs of A and B, then the last member in  $\mathcal{S}_2(A, B)$  is  $\operatorname{sres}_d(A, B)$ .

Remark 2.2.4 Proposition 2.2.3 can be directly proved by induction on the degree of B (see, [25]).

**Proposition 2.2.4** If d is the degree of the GCRDs of A and B, then the matrix

$$mat(X^{n-1}A, ..., XA, A, X^{m-1}B, ..., XB, B)$$

has rank (m+n-d).

**Proof** Let M be  $\max(X^{n-1}A, \ldots, XA, A, X^{m-1}B, \ldots, XB, B)$ . Since  $\operatorname{sres}_d(A, B)$  is nonzero. the rows of M represented by

$$X^{n-d-1}A, \ldots, A, X^{m-d-1}B, \ldots, B$$

are  $\mathcal{F}$ -linearly independent. Therefore, the rows of M represented by

$$X^{n-d-1}A, \ldots, A, X^{m-1}B, \ldots, X^{m-d-1}B, \ldots, B$$

are  $\mathcal{F}$ -linearly independent. We then have  $\operatorname{rank}(M) \geq m+n-d$ . On the other hand, there are non-zero  $U, V \in \mathcal{F}[X]$  such that  $A = U\operatorname{sres}_d(A, B)$  and  $B = V\operatorname{sres}_d(A, B)$  by Proposition 2.2.3. Therefore, the polynomials  $X^iA$   $(0 \leq i \leq n-1)$  and  $X^jB$   $(0 \leq j \leq m-1)$  are  $\mathcal{F}$ -linear combinations of  $X^{m+n-d-1}\operatorname{sres}_d(A, B), \ldots, X\operatorname{sres}_d(A, B), \operatorname{sres}_d(A, B)$ , and hence  $\operatorname{rank}(M) \leq m+n-d$ .

Corollary 2.2.5 If d is the degree of the GCRDs of A and B, then  $lc(sres_d(A, B))$  is a multiplicative bound for the denominators of the coefficients in the monic GCRD of A and B.

**Proof** If G is the monic GCRD of A and B, then G and  $\operatorname{sres}_d(A, B)$  are similar over  $\mathcal{F}$ . Thus,  $\operatorname{sres}_d(A, B) = \operatorname{lc}(\operatorname{sres}_d(A, B))G$  because G is monic.

The rest of this section is devoted to proving the theorem (Theorem 2.2.8) that describes the relation between the subresultant sequence of two Ore polynomials and that of their two left cofactors. This theorem will explain some experimental results in the next chapter. Chardin [5] proved this theorem when  $\mathcal{R}[X]$  is a ring of differential operators. Johnson [19] proved this theorem when  $\mathcal{R}[X]$  is a ring of algebraic polynomials. Our proof is inspired by Johnson's. First, we give two lemmas.

**Lemma 2.2.6** If G is a non-zero polynomial in  $\mathcal{F}[X]$ , then  $lc(BG) = lc(B)\sigma^n(lc(G))$ .

**Proof** Since  $lc(BG) = lc(B)lc(X^nG)$ , the lemma follows from the extended Leibniz rule.

**Lemma 2.2.7** If G is a non-zero polynomial in  $\mathcal{F}[X]$ , then

$$\operatorname{prem}(AG, BG) = (\sigma^{n} \operatorname{lc}(G))^{[m-n+1]} \operatorname{prem}(A, B)G. \tag{2.4}$$

Proof By the pseudo-remainder formula (1.6) we have

$$lc(B)^{[m-n+1]}A = PB + prem(A, B)$$
 (2.5)

and

$$lc(BG)^{[m-n+1]}AG = QBG + prem(AG, BG),$$
(2.6)

where P and Q belong to  $\mathcal{F}[X]$ . By (2.5) we obtain

$$\sigma^n(\mathrm{lc}(G))^{[m-n+1]}\mathrm{lc}(B)^{[m-n+1]}AG = \sigma^n(\mathrm{lc}(G))^{[m-n+1]}PBG + \sigma^n(\mathrm{lc}(G))^{[m-n+1]}\mathrm{prem}(A,B)G,$$

SO

$$lc(BG)^{[m-n+1]}AG = \sigma^n(lc(G))^{[m-n+1]}PBG + \sigma^n(lc(G))^{[m-n+1]}prem(A,B)G$$

by Lemma 2.2.6. Comparing this equation and (2.6) yields (2.4), because the pseudo-remainder of AG and BG is unique.  $\Box$ 

**Theorem 2.2.8** If G is a non-zero polynomial in  $\mathcal{F}[X]$ , with degree k, then

$$\operatorname{sres}_{k+i}(AG,BG) = \left(\sigma^{i+1}\operatorname{lc}(G)\right)^{[m+n-2i-1]}\operatorname{sres}_i(A,B)G \quad (n-1 \ge i \ge 0).$$

**Proof** Denote lc(G) by g,  $sres_{k+i}(AG, BG)$  by  $S_{k+i}$ , and  $sres_i(A, B)$  by  $T_i$ , for i = n - 1, n - 2, ..., 0. Put  $\alpha_{k+i} = lc(S_{k+i})$ ,  $\lambda_i = lc(T_i)$ , for  $i = n, n - 1, \ldots, 0$ ,  $\beta_{n+k} = (\sigma lc(S_{n+k}))^{[m-n]}$ ,  $\mu_n = (\sigma lc(T_n))^{[m-n]}$ ,  $\beta_{i+k} = \sigma lc(S_{k+i})$ , and  $\mu_i = \sigma lc(T_i)$ , for  $i = n - 1, n - 2, \ldots, 0$ . With the new notation, we need to show

$$S_{k+i} = (\sigma^{i+1}g)^{[m+n-2i-1]}T_iG, \quad (n-1 \ge i \ge 0).$$

If the sequence  $A, B, A_3, \ldots, A_l$  is a PRS of A and B, then the sequence  $AG, BG, A_3G, \ldots, A_lG$  is a PRS of AG and BG by Lemma 2.2.7. Hence, S(AG, BG) and S(A, B) have the same gap-structure by Theorem 1.4.2. In particular,  $S_{k+i} = 0$  if and only if  $T_i = 0$ , for  $n-1 \ge i \ge 0$ . Accordingly, we need only prove that the theorem holds for non-zero subresultants.

Let deg  $T_{n-1} = r \ge 0$ . First, we prove that the theorem holds for i = n - 1 and i = r. The theorem holds for i = n - 1 because of the following calculation:

$$S_{k+n-1} = (-1)^{m-n+1} \operatorname{prem}(AG, BG)$$
 (by Lemma 1.3.5)  
 $= (-1)^{m-n+1} (\sigma^n g)^{[m-n+1]} \operatorname{prem}(A, B) G$  (by Lemma 2.2.7)  
 $= (\sigma^n g)^{[m-n+1]} T_{n-1} G$  (by Lemma 1.3.5). (2.7)

By Theorem 1.4.2 we find

$$\beta_{k+n}^{[n-1-r]}S_{k+r}=\beta_{k+n-1}^{[n-1-r]}S_{k+n-1}\quad\text{and}\quad \mu_n^{[n-1-r]}T_r=\mu_{n-1}^{[n-1-r]}T_{n-1}.$$

Combining these two equations with equation (2.7) yields

$$\mu_{n-1}^{[n-1-r]}\beta_{k+n}^{[n-1-r]}S_{k+r} = \mu_n^{[n-1-r]}\beta_{k+n-1}^{[n-1-r]}(\sigma^n g)^{[m-n+1]}T_rG.$$

It remains to prove that

$$\left(\frac{\mu_n^{[n-1-r]}}{\beta_{k+n}^{[n-1-r]}}\right) \left(\frac{\beta_{k+n-1}^{[n-1-r]}}{\mu_{n-1}^{[n-1-r]}}\right) (\sigma^n g)^{[m-n+1]} = (\sigma^{r+1} g)^{[m+n-2r-1]}.$$
(2.8)

Denote by L the  $\sigma$ -factorial expression on the left-hand side of (2.8). Since

$$\frac{\beta_{k+n}}{\mu_n} = (\sigma^{n+1}g)^{[m-n]} \quad \text{and} \quad \frac{\beta_{k+n-1}}{\mu_{n-1}} = (\sigma^{n+1}g)^{[m-n+1]}(\sigma^{r+1}g)$$

by Lemma 2.2.6 and (2.7), we deduce

$$L = \left(\frac{(\sigma^{n+1}g)^{[m-n+1]}(\sigma^{r+1}g)}{(\sigma^{n+1}g)^{[m-n]}}\right)^{[n-1-r]} (\sigma^n g)^{[m-n+1]}$$

$$= \left((\sigma^{m+1}g)(\sigma^{r+1}g)\right)^{[n-1-r]} (\sigma^n g)^{[m-n+1]}$$

$$= (\sigma^{r+1}g)^{[n-1-r]} (\sigma^n g)^{[m-n+1]} (\sigma^{m+1}g)^{[n-1-r]} = (\sigma^{r+1}g)^{[m+n-2r-1]}.$$

This proves (2.8).

So far we have proved that the theorem holds for all i such that  $n-1 \ge i \ge r$ , because all the subresultants with orders between n-1 and r are all equal to zero. In particular, the theorem holds when n=1. Our induction hypothesis is that the theorem holds when  $\deg B < n$ . Assume that  $\deg B = n$ . To complete the induction, we have to prove that

$$S_{k+i} = (\sigma^{i+1}g)^{[m+n-2i-1]}T_iG, \quad (r-1 \ge i \ge 0).$$

By equation (1.19) in Lemma 1.4.1, we have, for  $r-1 \geq i \geq 0$ ,

$$lc(BG)^{[r-i]} (\sigma lc(BG))^{[n-1-i][m-n]} S_{k+i} = sres_{k+i} (BG, S_{k+n-1})$$
(2.9)

and

$$lc(B)^{[r-i]} (\sigma lc(B))^{[n-1-i][m-n]} T_i = sres_i(B, T_{n-1}).$$
(2.10)

From equation (2.9) we deduce

$$\begin{split} & \operatorname{lc}(BG)^{[r-i]} \left( \sigma \operatorname{lc}(BG) \right)^{[n-1-i][m-n]} S_{k+i} &= \operatorname{sres}_{k+i} (BG, S_{k+n-1}) \\ &= \operatorname{sres}_{k+i} \left( BG, (\sigma^n g)^{[m-n+1]} T_{n-1} G \right) \quad (\text{by (2.7)}) \\ &= (\sigma^n g)^{[m-n+1][n-i]} \operatorname{sres}_{k+i} \left( BG, T_{n-1} G \right) \quad (\text{by Lemma 1.3.3}) \\ &= (\sigma^n g)^{[m-n+1][n-i]} (\sigma^{i+1} g)^{[n+r-2i-1]} \operatorname{sres}_{k+i} \left( B, T_{n-1} \right) G \quad (\text{by the induction hypothesis}) \\ &= (\sigma^n g)^{[m-n+1][n-i]} (\sigma^{i+1} g)^{[n+r-2i-1]} \operatorname{lc}(B)^{[r-i]} \left( \sigma \operatorname{lc}(B) \right)^{[n-1-i][m-n]} T_i G \quad (\text{by (2.10)}). \end{split}$$

It remains to prove

$$\frac{(\sigma^{n}g)^{[m-n+1][n-i]}(\sigma^{i+1}g)^{[n+r-2i-1]}\operatorname{lc}(B)^{[r-i]}(\sigma\operatorname{lc}(B))^{[n-1-i][m-n]}}{\operatorname{lc}(BG)^{[r-i]}(\sigma\operatorname{lc}(BG))^{[n-1-i][m-n]}} = (\sigma^{i+1}g)^{[m+n-2i-1]}.$$
 (2.11)

Denote by L' the left-hand side of (2.11). By Lemma 2.2.6 it holds that

$$L' = \frac{(\sigma^n g)^{[m-n+1][n-i]}(\sigma^{i+1}g)^{[n+r-2i-1]}}{(\sigma^n g)^{[r-i]}(\sigma^{n+1}g)^{[n-1-i][m-n]}}.$$

The fourth assertion of Lemma 1.2.5 implies

$$(\sigma^n g)^{[m-n+1][n-i]} = (\sigma^n g)^{[m-i]} (\sigma^{n+1} g)^{[m-n][n-i-1]},$$

from which it follows that

$$L' = \left(\frac{(\sigma^n g)^{[m-i]}}{(\sigma^n g)^{[r-i]}}\right) (\sigma^{i+1} g)^{[n+r-2i-1]} = (\sigma^{i+1} g)^{[n+r-2i-1]} (\sigma^{[n+r-i]} g)^{[m-r]} = (\sigma^{i+1} g)^{[m+n-2i-1]}.$$

Equation (2.11) is proved.

This theorem reveals that if one uses the subresultant algorithm to compute the GCRD of two Ore polynomials, then one gets the subresultant sequence of the first kind of the two left cofactors as a byproduct. In particular, we have

Corollary 2.2.9 With the notation introduced in Theorem 2.2.8, we have

$$lc(sres_k(AG, BG))X^0 = lc(G)^{[m+n]}res(A, B).$$
 (2.12)

**Proof** Setting i = 0 in Theorem 2.2.8, we get  $\operatorname{sres}_k(AG, BG) = (\sigma g)^{[m+n-1]}\operatorname{res}(A, B)G$ . Equating the leading coefficients of both sides of this equation yields (2.12).

## 2.3 Least Common Left Multiples

Throughout this section the quotient field of  $\mathcal{R}$  is denoted by  $\mathcal{F}$  and  $(\mathcal{F}[X], \Theta, \sigma, \delta)$  is denoted by  $\mathcal{F}[X]$ . We assume that the degree of the GCRDs of A and B is equal to d.

**Definition 2.3.1** A non-zero polynomial in  $\mathcal{F}[X]$  of lowest degree, which is right-hand divisible by A and B, is called an LCLM of A and B.

Obviously, two LCLMs of A and B are similar over  $\mathcal{F}$ . Ore [33] proved the existence of LCLMs using the Euclidean algorithm. As a convenience for later references, we state his theorem [33, Theorem 8] in terms of polynomial remainder sequences.

**Theorem 2.3.1** With  $A = A_1$  and  $B = A_2$ , assume that the sequence

$$A_1, A_2, A_3, \ldots, A_k$$

is a PRS of A and B. Then the polynomial

$$L = A_{k-1}A_k^{-1}A_{k-2}A_{k-1}^{-1}\cdots A_3A_4^{-1}A_2A_3^{-1}A_1$$
 (2.13)

is an LCLM of A and B.

Ore proved that L in (2.13) was a well-defined polynomial and an LCLM of A and B. The proof of the following corollary can also be found in [33, p. 486].

Corollary 2.3.2 If L is an LCLM of A and B, then

$$\deg A + \deg B = d + \deg L.$$

Another way to compute LCLMs of A and B is to use the extended Euclidean algorithm to find U and V in  $\mathcal{F}[X]$  with  $\deg U = \deg(B) - d$  and  $\deg V = \deg(A) - d$  such that UA + VB = 0. Then both UA and VB are LCLMs of A and B by Corollary 2.3.2.

We shall now present a determinant formula for LCLMs. Let  $S_j = \text{sres}_j(A, B)$ , for j = n - 1,  $n - 2, \ldots, -1$ . By Remark 1.3.3 we have

$$S_j = u_{n-j-1}X^{n-j-1}A + \dots + u_1XA + u_0A + v_{m-j-1}X^{m-j-1}B + \dots + v_1XB + v_0B,$$

where each of the u's and v's belongs to R. In particular,

$$u_{n-j-1} = (-1)^{m-j} \sigma^{m-j-1}(\operatorname{lc}(B))\operatorname{coeff}(S_{j-1}, X^{j-1}), \tag{2.14}$$

where coeff( $S_{j-1}, X^{j-1}$ ) stands for the coefficient of  $X^{j-1}$  in  $S_{j-1}$ . Using multiplication in  $\mathcal{F}[X]$  we write

$$U_j A + V_j B = S_j, (2.15)$$

where  $U_j = u_{n-j-1}X^{n-j-1} + \cdots + u_1X + u_0$  and  $V_j = v_{m-j-1}X^{m-j-1} + \cdots + v_1X + v_0$ . The polynomials  $U_j$  and  $V_j$  can be expressed by replacing the last column in the determinant of  $S_j$  by the transposes of

$$(X^{n-j-1}, X^{n-j-2}, \dots, X^0, \underbrace{0, 0, \dots, 0}_{m-j})$$

and

$$(\underbrace{0, 0, \ldots, 0}_{n-j}, X^{m-j-1}, X^{m-j-2}, \ldots, X^{0}),$$

respectively.

**Proposition 2.3.3** Both  $U_{d-1}A$  and  $V_{d-1}B$  are LCLMs of A and B.

**Proof** Since  $S_d$  is a GCRD of A and B by Proposition 2.2.3, we see that  $S_{d-1} = 0$ . Therefore,  $U_{d-1}A + V_{d-1}B = 0$  by (2.15). Since the coefficient of  $X^{n-d}$  in  $U_{d-1}$  is nonzero by (2.14) and Proposition 2.2.3,  $\deg U_{d-1} = n - d$ , consequently,  $\deg U_{d-1}A = m + n - d$ . Thus  $U_{d-1}A$  is an LCLM of A and B by Corollary 2.3.2.

In the next chapter we show that the GCRDs of A and B can be obtained without computing any PRS of A and B when R is  $\mathbf{Z}[t]$ . In this case we need only to expand a determinant to compute LCLMs. As the leading coefficient of an LCLM is particularly important for proving identities of holonomic functions, we give a multiplicative bound for the denominators of the coefficients in the monic LCLM of A and B.

Corollary 2.3.4 If L is the monic LCLM of A and B, then  $bL \in \mathcal{R}[X]$ , where

$$b = \left(\sigma^{m-d} \mathrm{lc}(B)\right) \left(\sigma^{n-d} \mathrm{lc}(A)\right) \mathrm{lc}(\mathrm{sres}_d(A,B)).$$

**Proof** By (2.14) we have

$$lc(U_{d-1}A) = (-1)^{m-j} \left(\sigma^{m-d}lc(B)\right) \left(\sigma^{n-d}lc(A)\right) lc(sres_d(A, B))$$

because deg  $U_{d-1} = n - d$ . The lemma then follows from the fact that any two LCLMs of A and B are similar over  $\mathcal{F}$ .

In the rest of this section, we present an algorithm for computing  $U_{d-1}A$ , Let  $d_i = \deg A_i$ , where  $A_i$  is given in Theorem 2.3.1, for i = 1, 2, ..., k. Theorem 1.4.7 and Corollary 1.4.4 imply that  $S_1(A, B)$  consists of

$$A, B, S_{d_2-1}, S_{d_3-1}, \ldots, S_{d_{k-1}-1}$$

and that  $S_2(A, B)$  consists of

$$A, B, S_{d_3}, S_{d_4}, \ldots, S_{d_k}.$$

**Lemma 2.3.5** For all i with  $2 \le i \le k$ ,  $\deg U_{d_{i-1}} = n - d_i$  and  $\deg V_{d_{i-1}} = m - d_i$ , where  $U_{d_{i-1}}$  and  $V_{d_{i-1}}$  are defined in (2.15).

**Proof** It follows from (2.14) and the fact that  $S_{d_i}$  is regular.

**Theorem 2.3.6** For  $i=2, 3, \ldots, k-1$ , let  $a_{i+1}$  be  $lc(S_{d_{i-1}})$  and  $U_{d_{i-1}}$  be the same as those defined by (2.15). Let  $e_3, e_4, \ldots, e_k$  form the sequence satisfying

$$e_3S_{d_2-1} = \operatorname{prem}(A, B),$$
 (2.16)

$$e_4 S_{d_3-1} = \text{prem}(B, S_{d_2-1}),$$
 (2.17)

$$e_i S_{d_{i-1}-1} = \operatorname{prem}(S_{d_{i-3}-1}, S_{d_{i-2}-1}),$$
 (2.18)  
 $for \ i = 5, 6, \dots, k,$ 

then

$$U_{d_2-1} = (-\mathrm{lc}(B))^{[m-n+1]}$$
 (2.19)

$$U_{d_3-1} = -e_4^{-1}Q_4U_{d_2-1} (2.20)$$

$$U_{d_{i-1}-1} = e_i^{-1} \left( a_{i-1}^{[d_{i-2}-d_{i-1}+1]} U_{d_{i-3}-1} - Q_i U_{d_{i-2}-1} \right),$$

$$for i = 5, 6, \dots, k$$

$$(2.21)$$

where  $Q_4$  is the left pseudo-quotient of B and  $S_{d_2-1}$ , and each of the  $Q_i$ 's is the left pseudo-quotient of  $S_{d_{i-3}-1}$  and  $S_{d_{i-2}-1}$ . Furthermore, if  $H_k = a_k^{[d_{k-1}-d_k+1]}U_{d_{k-2}-1} - Q_{k+1}U_{d_{k-1}-1}$ , where  $Q_{k+1}$  is the left pseudo-quotient of  $S_{d_{k-2}-1}$  and  $S_{d_{k-1}-1}$ , then

$$U_{d_k-1} = (-1)^{m-d_k+1} \operatorname{lc}(S_{d_k}) \left(\sigma^{m-d_k} \operatorname{lc}(B)\right) \operatorname{lc}(H_k)^{-1} H_k.$$
(2.22)

**Proof** We say that two Ore polynomials F and G are congruent modulo an Ore polynomial M on the right if F - G is right-divisible by M, which is denoted by  $F \equiv G \pmod{M}$ .

The equality (2.19) holds by the definition of  $U_{d_2-1}$ . Assume that k > 3. By (2.16) and (2.17) we have

$$U_{d_2-1}A \equiv S_{d_2-1} \pmod{B}$$
 and  $Q_4S_{d_2-1} \equiv -e_4S_{d_3-1} \pmod{B}$ .

Combining the two equations just derived yields  $-e_4^{-1}Q_4U_{d_2-1}A\equiv S_{d_3-1}\pmod B$ . On the other hand, the definition of  $U_{d_3-1}$  implies that  $U_{d_3-1}A\equiv S_{d_3-1}\pmod B$ . It follows that

$$C_4 A \equiv 0 \pmod{B}$$
,

where  $C_4 = -e_4^{-1}Q_4U_{d_2-1} - U_{d_3-1}$ . But  $C_4 = 0$ , otherwise  $C_4A$  would be a non-zero left common multiple of A and B, with degree  $\leq (m+n-d_3)$ , which contradicts Corollary 2.3.2. Equation (2.20) holds.

Consider the case in which k > 4. For  $5 \le i \le k$ , the congruent relations

$$U_{d_{i-3}-1}A \equiv S_{d_{i-3}-1} \pmod{B}$$
 and  $U_{d_{i-2}-1}A \equiv S_{d_{i-2}-1} \pmod{B}$ .

hold by (2.15). Furthermore, equation (2.18) can be written as

$$a_{i-1}^{[d_{i-2}-d_{i-1}+1]}S_{d_{i-3}-1}=Q_{i}S_{d_{i-2}-1}+e_{i}S_{d_{i-1}-1}.$$

Combining the two congruent equations and the equation just given yields

$$e_i^{-1} \left( a_{i-1}^{[d_{i-2}-d_{i-1}+1]} U_{d_{i-3}-1} - Q_i U_{d_{i-2}-1} \right) A \equiv S_{d_{i-1}-1} \pmod{B}.$$

The congruence just proved and  $U_{d_{i-1}-1}A\equiv S_{d_{i-1}-1}\ (\mathrm{mod}\ B)$  imply that

$$C_i A \equiv 0 \pmod{B}$$
,

where  $C_i = U_{d_{i-1}-1} - e_i^{-1} \left( a_{i-1}^{[d_{i-2}-d_{i-1}+1]} U_{d_{i-3}-1} - Q_i U_{d_{i-2}-1} \right)$ . Since

$$\deg U_{d_{i-1}-1} = \deg \left( a_{i-1}^{[d_{i-2}-d_{i-1}+1]} U_{d_{i-3}-1} - Q_i U_{d_{i-2}-1} \right) = n - d_{i-1}$$

by Lemma 2.3.5, we have  $C_i = 0$ , otherwise the degree of the LCLMs of A and B would be not greater than  $(n - d_{i-1})$ , which contradicts to Corollary 2.3.2. Equation (2.21) holds.

To prove (2.22), we let 
$$C_k = (-1)^{m-d_k+1} \left(\sigma^{m-d_k} \operatorname{lc}(B)\right) \operatorname{lc}(S_{d_{k-1}-1}) \operatorname{lc}(H_k)^{-1} H_k$$
. Observe that 
$$a_k^{[d_{k-1}-d_k+1]} S_{d_{k-2}-1} = Q_{k+1} S_{d_{k-1}-1}$$

because  $S_{d_{k-1}-1}$  is the last member of  $S_1(A,B)$ . It then follows from the congruent equations

$$U_{d_{k-2}-1}A \equiv S_{d_{k-2}-1} \pmod{B}$$
 and  $U_{d_{k-1}-1}A \equiv S_{d_{k-2}-1} \pmod{B}$ 

that  $H_k A \equiv 0 \pmod{B}$ . The degree of  $H_k$  is equal to  $(n-d_k)$  since

$$\deg(Q_{k+1}U_{d_{k-1}-1}) = (d_{k-1}-d_k) + (n-d_{k-1}) = n-d_k \quad \text{and} \quad \deg U_{d_{k-2}-1} = n-d_{k-2}.$$

Accordingly, the product  $H_kA$  is an LCLM of A and B. Notice that  $lc(C_k) = lc(U_{d_k-1})$ . Hence  $C_k$  and  $U_{d_k-1}$  are equal because  $C_kA$  and  $U_{d_k-1}A$  are similar over  $\mathcal{F}$ .

As the  $e_i$ 's in Theorem 2.3.6 can be constructed by the subresultant algorithm, we perform the subresultant algorithm, and record both left pseudo-quotient  $Q_i$  and extraneous factor  $e_i$  after each pseudo-division. Compute  $U_{d_i-1}$ , by (2.19), (2.20) and (2.21). Ultimately, we get both  $U_{d_{k-2}-1}$  and  $U_{d_{k-1}-1}$ . The leading coefficient of  $S_{d_k}$  can be obtained from the formula given in Lemma 1.4.6, so  $U_{d_k-1}$  is computed by (2.22).

# Chapter 3

# Modular Algorithm for Computing GCRDs over $\mathbf{Z}[t]$

Recent years have seen a rapid development of the algorithms for manipulating the functions that are annihilated by linear operational polynomials [42, 38, 2, 6]. This development motivates us to design an efficient algorithm for computing GCRDs over  $\mathbf{Z}[t]$ . The GCRD-calculation plays an important role in the computation of linear operational polynomials. For instance, if  $L_1$  and  $L_2$  are two linear differential operators, then their GCRD corresponds to the intersection of the solution spaces of  $L_1$  and  $L_2$ . To represent the sum of the two solution spaces, one needs an LCLM of  $L_1$  and  $L_2$ , which can be expressed as a determinant with entries being the derivatives of coefficients of  $L_1$  and  $L_2$ , as long as the GCRD is obtained (see, Section 2.3). The greatest common left divisor of  $L_1$  and  $L_2$  can be obtained from the GCRD of their adjoint operators.

We will extend the techniques used in the modular algorithm for computing usual commutative polynomial GCDs as much as we can (see, Brown [3] and Geddes et al [16]). Two new problems that cannot be tackled by the classical techniques, are that

- evaluation mappings are not Ore ring homomorphisms
- the normalization of leading coefficients is different from that in the algebraic case.

The first problem will be solved by the subresultant theory for Ore polynomials; the second one by rational number and rational function reconstructions. To the author's knowledge the present algorithm is the first modular algorithm for computing Ore polynomial GCRDs. The non-modular

<sup>&</sup>lt;sup>1</sup>This chapter reports joint work with István Nemes.

algorithms are the Euclidean algorithm [33] and subresultant algorithm. Grigor'ev [18] presents a method for computing the GCRD of several linear differential operators by Gaussian elimination.

We will work in Ore polynomial rings whose ground domains are algebraic polynomial rings. Throughout this section, p is a prime and  $\mathbf{Z}_p$  is the Galois field with p elements. For an indeterminate t,  $\mathbf{Z}[t]$  and  $\mathbf{Z}_p[t]$  are the rings of algebraic polynomials in t over  $\mathbf{Z}$  and  $\mathbf{Z}_p$ , respectively. Let X be a new indeterminate. For non-zero F in  $\mathbf{Z}[t][X]$  or  $\mathbf{Z}_p[t][X]$ , the leading coefficient of F in X is denoted by  $\mathrm{lc}(F)$ , the leading coefficient of  $\mathrm{lc}(F)$  in t is called the head coefficient of F and denoted by  $\mathrm{hc}(F)$ , the degree of F in X is denoted by  $\mathrm{deg}_{F}$ , and the degree of F in t is denoted by  $\mathrm{deg}_{t}$  F.

We assume that  $(\mathbf{Z}[t][X], \sigma, \delta)$  is an Ore polynomial ring over  $\mathbf{Z}[t]$ . For brevity we denote this ring by  $\mathbf{Z}[t][X]$ . If A and B are in  $\mathbf{Z}[t][X]$ , then the normalized GCRD of A and B is the GCRD of A and B, which is in  $\mathbf{Z}[t][X]$  and primitive with respect to X, and has positive head coefficient. If A and B are in the Ore polynomial ring  $\mathbf{Z}_p[t][X]$ , then the normalized GCRD of A and B is the GCRD of A and B, which is in  $\mathbf{Z}_p[t][X]$  and primitive with respect to X, and has head coefficient 1. The normalized GCRD of A and B, where A and B are in  $\mathbf{Z}[t][X]$  or  $\mathbf{Z}_p[t][X]$ , is denoted by  $\mathrm{GCRD}(A, B)$ .

The idea of our algorithm is as follows.

- 1. Use sufficiently many modular homomorphisms to reduce GCRD problem in  $\mathbf{Z}[t][X]$  to a series of GCRD problems in  $\mathbf{Z}_p[t][X]$ .
- 2. Use sufficiently many evaluation mappings to reduce GCRD problem in  $\mathbf{Z}_p[t][X]$  to a series of the problems of finding evaluation homomorphic images of the monic associate of the sought-after GCRD.
- 3. Use Chinese Remainder Algorithm (CRA) and rational function reconstruction to combine the lucky evaluation homomorphic images.
- 4. Use CRA and rational number reconstruction to combine the lucky modular homomorphic images.

This chapter is organized as follows. In Section 3.1, we study the modular and evaluation mappings. Section 3.2 is devoted to presenting the algorithm for computing the evaluation homomorphic images of the monic associate of the GCRD of two Ore polynomials in  $\mathbf{Z}_p[t][X]$ . In Section 3.3, we review the rational number and function reconstructions. The modular algorithms

for computing GCRDs in  $\mathbf{Z}_p[t][X]$  and in  $\mathbf{Z}[t][X]$  are described in Section 3.4 and Section 3.5. respectively. Experimental results are given in Section 3.6

## 3.1 Modular Mappings and Evaluation Mappings

A modular mapping  $\phi_p$  from  $\mathbf{Z}[t][X]$  to  $\mathbf{Z}_p[t][X]$  is a module homomorphism defined for a prime p by  $\phi_p(A) = A \mod p$ , for  $A \in \mathbf{Z}[t][X]$ . An evaluation mapping  $\phi_{t-k}$  from  $\mathbf{Z}_p[t][X]$  to  $\mathbf{Z}_p[X]$  is a module homomorphism defined for an element k of  $\mathbf{Z}_p$  by  $\phi_{t-k}(A(t,X)) = A(k,X)$ , for  $A \in \mathbf{Z}_p[t][X]$ . In this section, we investigate whether modular and evaluation mappings can be regarded as Ore ring homomorphisms.

The next lemma clearly holds because  $\sigma$  and  $\delta$  are endomorphisms of the additive group  $\mathbf{Z}[t]$ .

**Lemma 3.1.1** If  $f, g \in \mathbf{Z}[t]$  and  $f \equiv g \mod p$ , then  $\sigma(f) \equiv \sigma(g) \mod p$  and  $\delta(f) \equiv \delta(g) \mod p$ .

This lemma allows us to define two operators  $\sigma_p$  and  $\delta_p$  on  $\mathbf{Z}_p[t]$  by the respective rules:

$$\sigma_p(\phi_p(f)) = \phi_p(\sigma(f))$$
 and  $\delta_p(\phi_p(f)) = \phi_p(\delta(f)),$  for all  $f \in \mathbf{Z}[t].$ 

It is clear that  $\sigma_p$  is an endomorphism of the domain  $\mathbf{Z}_p[t]$  and that  $\delta_p$  is a pseudo-derivation with respect to  $\sigma_p$  if  $\sigma_p$  is injective.

**Lemma 3.1.2** If p is not a divisor of  $hc(\sigma(t))$ , then  $\sigma_p$  is injective.

**Proof** Since  $\sigma(m) = m$ , for  $m \in \mathbb{Z}$ ,  $\deg_t \sigma(t) > 0$ . Let  $f = f_n t^n + \dots + f_0 \in \mathbb{Z}[t]$ . If  $\sigma_p(\phi_p(f)) = 0$ , then  $\phi_p(f_n \sigma(t)^n + \dots + f_0) = 0$  by the definition of  $\sigma_p$ . Since  $\phi_p(\operatorname{hc}(\sigma(t))) \neq 0$ ,  $\phi_p(\sigma(t))$  is of positive degree in t, and hence  $\phi_p(f_i) = 0$ ,  $0 \le i \le n$ .

The above two lemmas assert that  $\sigma_p$  is a conjugate operator and  $\delta_p$  is a pseudo-derivation with respect to  $\sigma_p$  if p does not divide  $hc(\sigma(t))$ . Thus,  $(\mathbf{Z}_p[t][X], \sigma_p, \delta_p)$  is an Ore polynomial ring with the multiplication defined by  $Xa = \sigma_p(a)X + \delta_p(a)$ , for all  $a \in \mathbf{Z}_p[t]$  (see, Proposition 1.2.1 and Theorem 1.2.2).

When  $\sigma_p$  is injective, the Ore polynomial ring  $(\mathbf{Z}_p[t][X], \sigma_p, \delta_p)$  is said to be the *induced Ore* polynomial ring from  $\mathbf{Z}[t][X]$  by the modular homomorphism  $\phi_p$ . The next corollary is evident.

Corollary 3.1.3 If  $(\mathbf{Z}_p[t][X], \sigma_p, \delta_p)$  is the induced Ore polynomial ring from  $\mathbf{Z}[t][X]$  by the modular mapping  $\phi_p$ , then  $\phi_p$  is an Ore polynomial ring homomorphism from  $\mathbf{Z}[t][X]$  to  $\mathbf{Z}_p[t][X]$ .

If  $(\mathbf{Z}_p[X], \sigma', \delta')$  is an Ore polynomial ring, then  $\sigma'$  must be the identity mapping and  $\delta'$  must be the null mapping since  $\mathbf{Z}_p$  is generated by 1 as an additive group. Accordingly, the multiplication induced by  $\sigma'$  and  $\delta'$  is the usual commutative one. Therefore, an evaluation mapping from an Ore polynomial ring  $\mathbf{Z}_p[t][X]$  to  $\mathbf{Z}_p[X]$  is not always an Ore ring homomorphism. This fact tells us that the algebraic modular method in [3] cannot be directly applied to Ore polynomials. We will overcome this difficulty by Propositions 2.2.3 and 2.2.4.

## 3.2 Evaluation Homomorphic Images of GCRDs

In this section, let  $(\mathbf{Z}_p[t][X], \sigma_p, \delta_p)$  be an Ore polynomial ring. Fix an element k of  $\mathbf{Z}_p$  and the evaluation mapping  $\phi_{t-k}$ . Assume that A and B are in  $\mathbf{Z}_p[t][X]$ , with deg A=m and deg B=n, where  $m \geq n \geq 1$ . Let M be the matrix  $\max(X^{n-1}A, \ldots, XA, A, X^{m-1}B, \ldots, XB, B)$ . We show how to use the arithmetic in  $\mathbf{Z}_p$  to compute the monic associate of  $\phi_{t-k}(\operatorname{GCRD}(A, B))$ .

**Lemma 3.2.1** Let G be GCRD(A, B) with degree d and let  $S_d$  be  $sres_d(A, B)$ . If  $\phi_{t-k}(lc(S_d))$  is nonzero, then

$$\frac{\phi_{t-k}(G)}{\phi_{t-k}(\operatorname{lc}(G))} = \frac{\phi_{t-k}(S_d)}{\phi_{t-k}(\operatorname{lc}(S_d))}.$$

**Proof** By Proposition 2.2.3 there exists a non-zero r in  $\mathbf{Z}_p[t]$  such that  $rG = S_d$ . Since  $\phi_{t-k}(\mathrm{lc}(S_d))$  is nonzero,  $\phi_{t-k}(\mathrm{lc}(G))$  is nonzero. Applying  $\phi_{t-k}$  to

$$\frac{G}{\operatorname{lc}(G)} = \frac{S_d}{\operatorname{lc}(S_d)}$$

yields the lemma.

**Definition 3.2.1** Let d be the degree of GCRD(A, B). The evaluation point k is unlucky for A and B if either

$$\phi_{t-k}\left(\prod_{i=0}^{m-1}\left(\sigma_p^i\mathrm{lc}(B)\right)\right)=0\quad\text{or}\quad\phi_{t-k}(\mathrm{lc}(\mathrm{sres}_d(A,B)))=0.$$

One way to compute the image of the monic associate of GCRD(A, B) under  $\phi_{t-k}$  is as follows. We compute the image of M under  $\phi_{t-k}$ , denoted by  $M_{t-k}$ , and compute the rank of  $M_{t-k}$ . If k is not unlucky, then M and  $M_{t-k}$  have the same rank, so the degree of GCRD(A, B), say, d, is equal to  $(m + n - \text{rank}(M_{t-k}))$  by Proposition 2.2.3. Thus, the monic associate of  $\phi_{t-k}(\text{sres}_d(A, B))$  is the monic associate of  $\phi_{t-k}(GCRD(A, B))$  by Lemma 3.2.1. This method has two computational tasks, namely, calculating  $\text{rank}(M_{t-k})$  and  $\phi_{t-k}(\text{sres}_d(A, B))$ . These two tasks can be combined

into one Gaussian elimination when the pivot rows are chosen properly. These considerations lead to the algorithm GCRD\_e.

#### algorithm GCRD\_e

**Input:** A prime p, a residue  $k \in \mathbb{Z}_p$ , and  $A, B \in \mathbb{Z}_p[t][X]$  with  $\deg A \ge \deg B \ge 0$ .

**Output:**  $g \in \mathbf{Z}_p[X]$ . If k is not unlucky, then g is the monic associate of  $\phi_{t-k}(\operatorname{GCRD}(A,B))$ . Otherwise, g is 0 or of degree greater than d.

[initialize]

- 1.  $m \leftarrow \deg A$ ;  $n \leftarrow \deg B$ ;
- 2. for i = 0 to m 1 do {  $C_i \leftarrow \phi_{t-k}(X^iB)$ ; if  $\deg C_i < n + i$  then return(0); [unlucky k] } [nested elimination]
- 3. for i = 0 to n 1 do {
- 4.  $R_i \leftarrow \phi_{t-k}(X^i A);$
- 5. for j = m n + i to 0 do { if  $\deg(R_i) = \deg(C_j)$  then  $R_i \leftarrow R_i \operatorname{lc}(R_i)\operatorname{lc}(C_j)^{-1}C_j$ ; }
- 6. while  $\exists l, 0 \le l \le i-1$  and  $\deg R_i = \deg R_l \ge 0$  do  $\{R_i \leftarrow R_i \operatorname{lc}(R_i)\operatorname{lc}(R_l)^{-1}R_l;\}$  [compute the rank]
- 7.  $r \leftarrow m + n$ ;
- 8. for i = 0 to n 1 do { if  $R_i = 0$  then  $r \leftarrow r 1$ ; }

[guess the degree]

9.  $b \leftarrow m + n - r$ ;

[compute the image]

- 10.  $g \leftarrow$  the polynomial of least degree in the set  $\{R_0, R_1, \ldots, R_{n-b-1}, C_0\}$ ;
- 11. if  $\deg g = b$  then  $g \leftarrow \operatorname{lc}(g)^{-1}g$ ; else  $g \leftarrow 0$ ;
- 12. return(g);

Proposition 3.2.2 The algorithm GCRD\_e is correct.

**Proof** Let  $d = \deg \operatorname{GCRD}(A, B)$  and  $S_d = \operatorname{sres}_d(A, B)$ . We exclude the case when  $\phi_{t-k}(\sigma^i \operatorname{lc}(B))$  is zero, for some i with  $0 \le i \le m-1$ . Thus,  $\deg C_i = n+i$ , for  $i=0, 1, \ldots, m-1$ . According to lines 5 and 6, all of the non-zero  $R_j$ 's have distinct degrees less than n, for  $j=0, 1, \ldots, n-1$ . Hence r obtained from line 8 is the rank of  $N_{t-k}$ , where

$$N_{t-k} = \max(R_{n-1}, \ldots, R_0, C_{m-1}, \ldots, C_0).$$

Let

$$M_{t-k} = \max(\phi_{t-k}(X^{n-1}A), \ldots, \phi_{t-k}(A), \phi_{t-k}(X^{m-1}B), \ldots, \phi_{t-k}(B)).$$

Then  $r = \operatorname{rank}(M_{t-k})$  because  $N_{t-k}$  is computed by row reduction on  $M_{t-k}$  in lines 3, 4, 5 and 6. Note that  $r \leq \operatorname{rank}(M)$ . Consequently, the tentative degree b obtained from line 9 is not less than d by Proposition 2.2.4. Notice that the polynomial g obtained from line 10 is the polynomial with smallest degree among the polynomials

$$R_{n-b-1}, \ldots, R_0, C_{m-b-1}, \ldots, C_0,$$

all of which are  $\mathbf{Z}_p$ -linear combinations of

$$\phi_{t-k}(X^{n-b-1}A), \ldots, \phi_{t-k}(A), \phi_{t-k}(X^{m-b-1}B), \ldots, \phi_{t-k}(B),$$

and vice versa. Therefore, g and  $\phi_{t-k}(\operatorname{sres}_b(A, B))$  are similar over  $\mathbf{Z}_p$  by Lemma 1.3.4. If k is not unlucky, then the polynomials

$$\phi_{t-k}(X^{n-d-1}A), \ldots, \phi_{t-k}(A), \phi_{t-k}(X^{m-d-1}B), \ldots, \phi_{t-k}(B)$$

are  $\mathbf{Z}_p$ -linearly independent, because  $\phi_{t-k}(\operatorname{lc}(S_d))$  is nonzero. Accordingly, the polynomials

$$\phi_{t-k}(X^{n-d-1}A), \ldots, \phi_{t-k}(A), \phi_{t-k}(X^{m-1}B), \ldots, \phi_{t-k}(X^{m-d-1}B), \ldots, \phi_{t-k}(B)$$

are  $\mathbb{Z}_p$ -linearly independent. Hence  $r \geq m+n-d$ . But  $\operatorname{rank}(M) = m+n-d$  by Proposition 2.2.4. Consequently,  $r = \operatorname{rank}(M)$ , so b = d. Since g and  $\phi_{t-k}(S_d)$  are similar over  $\mathbb{Z}_p$ , g returned in line 12 is the monic associate of  $\phi_{t-k}(\operatorname{GCRD}(A, B))$  by Lemma 3.2.1.

If k is unlucky, then there are two cases, namely, b>d or b=d. In the former case, g is either 0 or a polynomial of degree greater than d. In the latter case,  $\deg g< b$  since g and  $\phi_{t-k}(S_d)$  are similar over  $\mathbf{Z}_p$ , and  $\deg \phi_{t-k}(S_d)< d$ . Therefore, g is set to be 0 in line 11.

## 3.3 Rational Number and Rational Function Reconstructions

To use CRA to combine the evaluation homomorphic images of the monic GCRD of two Ore polynomials, say, A and B in  $\mathbb{Z}_p[t][X]$ , we need to know a multiplicative bound for the denominator of the monic GCRD of A and B. In the algebraic case, such a bound is the GCD of lc(A) and lc(B). However, there are counterexamples showing that neither the GCD nor the LCM of lc(A) and lc(B) is the desired multiplicative bound. One multiplicative bound is the leading coefficient of the dth

subresultant of A and B if GCRD(A, B) has degree d (see, Corollary 2.2.5). Unfortunately, this multiplicative bound tends to be loose. Inspired by the work of Encarnación [14, 15], we use rational function reconstruction to combine the evaluation homomorphic images of GCRD(A, B). A similar problem arises when A and B are in  $\mathbf{Z}[t][X]$ . Thus, the rational number reconstruction is also needed.

The algorithm for reconstructing rational numbers, due to Wang [40], is recorded in the algorithm RECON\_n.

#### algorithm RECON\_n

Input: A modulus  $m \in \mathbb{N}^+$  and a non-zero residue  $r \in \mathbb{Z}_m = \{0, 1, ..., m-1\}$ .

Output: A pair (a, b) of integers, s.t.  $ab^{-1} = r$  in  $\mathbb{Z}_m$ ,  $|a| < \sqrt{m/2}$ , and  $0 < b < \sqrt{m/2}$  if such a and b exist. Otherwise, NIL is returned.

```
1. a_1 \leftarrow m; a_2 \leftarrow r; v_1 \leftarrow 0; v_2 \leftarrow 1; i \leftarrow 2;
```

2. while true do {

3. if  $v_i \geq \sqrt{m/2}$  then return(NIL);

4. if  $a_i < \sqrt{m/2}$  and  $GCD(a_i, v_i) = 1$  then return  $((sign(v_i)a_i, |v_i|));$ 

5.  $q \leftarrow \text{integral quotient of } a_{i-1} \text{ and } a_i;$ 

6.  $a_{i+1} \leftarrow a_{i-1} - qa_i; v_{i+1} \leftarrow v_{i-1} - qv_i; i \leftarrow i+1;$ 

According to [12], we added the condition  $GCD(a_i, v_i) = 1$  in line 4 in RECON\_n, because Wang's original algorithm does not guarantee that GCD(b, m) = 1. The reader is advised to consult [12] for more detailed discussion and recent progress on rational number reconstruction.

In the library of the computer algebra system *Maple*, there is an implementation solving the general problem of rational function reconstruction. As we could not find any proof of the correctness of this implementation in the literature, we present the problem of rational function reconstruction and a modified version of the algorithm, named RECON\_f, for our use,

We are concerned with the following problem.

**Problem RFR:** Let  $\mathcal{F}$  be a field and  $\mathcal{F}[t]$  the algebraic polynomial ring over  $\mathcal{F}$ .

Given:  $M \in \mathcal{F}[t]$  with  $\deg_t M > 0$ , and a non-zero  $R \in \mathcal{F}[t]/(M)$ .

Find:  $A, B \in \mathcal{F}[t]$  with  $\deg_t A \leq (\deg_t M)/2$ ,  $\deg_t B < (\deg_t M)/2$ , and GCD(B, M) = 1 such that  $AB^{-1} = R$  in  $\mathcal{F}[t]/(M)$ .

The algorithm RECON\_f solves Problem RFR.

#### algorithm RECON\_f

Input: A modulus  $M \in \mathcal{F}[t]$  and a non-zero residue  $R \in \mathcal{F}[t]/(M)$ .

Output: A pair (A, B) of polynomials in  $\mathcal{F}[t]$ , such that  $AB^{-1} = R$  in  $\mathcal{F}[t]/(M)$ , lc(B) = 1,  $\deg_t A \leq (\deg_t M)/2$ , and  $\deg_t B < (\deg_t M)/2$  if such A and B exist. Otherwise, NIL is returned.

- 1.  $A_1 \leftarrow M$ ;  $A_2 \leftarrow R$ ;  $V_1 \leftarrow 0$ ;  $V_2 \leftarrow 1$ ;  $i \leftarrow 2$ ;
- 2. while true do
- 3. if  $\deg_t V_i \ge (\deg_t M)/2$  then return(NIL);
- 4. if  $\deg_t A_i \leq (\deg_t M)/2$  and  $GCD(A_i, V_i) = 1$  then return  $(((\operatorname{lc}_t V_i)^{-1} A_i, (\operatorname{lc}_t V_i)^{-1} V_i));$
- 5.  $Q \leftarrow \text{polynomial quotient of } A_{i-1} \text{ and } A_i$ ;
- 6.  $A_{i+1} \leftarrow A_{i-1} QA_i; V_{i+1} \leftarrow V_{i-1} qV_i; i \leftarrow i+1;$

Now, we prove the correctness of RECON\_f.

**Lemma 3.3.1** If (A, B) is a solution to Problem RFR, then the fraction A/B is uniquely determined, and the pair (A/GCD(A, B), B/GCD(A, B)) is also a solution.

**Proof** Suppose that (A, B) and (A', B') are two solutions to Problem RFR. Then  $BR \equiv A \mod M$  and  $B'R \equiv A' \mod M$ . It follows that  $B'A \equiv BA' \mod M$ . Hence, B'A = BA' because both  $\deg_t AB'$  and  $\deg_t A'B$  are smaller than  $\deg_t M$ .

To prove that  $(A/\mathrm{GCD}(A,B),B/\mathrm{GCD}(A,B))$  is also a solution to the same problem, we observe that there is  $C \in \mathcal{F}[t]$  such that CM + BR = A. Since  $\mathrm{GCD}(B,M) = 1$ ,  $\mathrm{GCD}(A,B)$  divides C.  $\square$ 

RECON\_f is the half-extended Euclidean algorithm equipped with a different terminating condition. In order to prove the correctness of RECON\_f, one has to prove that if there exists a solution (A, B) to Problem RFR, then A and a member in a PRS of M and R are similar over  $\mathcal{F}$ . By the algebraic subresultant theory it is sufficient to show that A and a non-zero subresultant of M and R are similar over  $\mathcal{F}$ .

**Lemma 3.3.2** Let  $\deg_t M = m$  and  $\deg_t R = n$ , where  $m > n \ge 0$ . Assume that (A, B) is a solution to Problem RFR and GCD(A, B) = 1. If  $\deg_t B = m - j - 1$ , then  $A \sim_{\mathcal{F}} \operatorname{sres}_j(M, R)$ .

**Proof** There exists C in  $\mathcal{F}[t]$ , with degree (n-j-1), such that

$$CM + BR = A. (3.1)$$

Let  $\deg_t A = d$  and write

$$A = \sum_{i=0}^{d} a_i t^i$$
,  $B = \sum_{i=0}^{m-j-1} b_i t^i$ , and  $C = \sum_{i=0}^{n-j-1} c_i t^i$ ,

where  $a_d$ ,  $b_{m-j-1}$ , and  $c_{m-j-1}$  are all nonzero. Note that  $d \leq j$  since m-j-1 < m/2 and  $d \leq m/2$ . Let

$$\mathbf{u} = (c_{n-j-1}, \dots, c_0, b_{m-j-1}, \dots, b_0)$$

and

$$\mathbf{v} = (\underbrace{0, \dots, 0,}_{m+n-i-d-1} a_d, a_{d-1}, \dots, a_0).$$

Moreover, let N be the  $(m+n-2j)\times (m+n-j)$  matrix

$$\max(t^{n-j-1}M, ..., M, t^{m-j-1}R, ..., R).$$

Then equation (3.1) can be written as the linear system

$$\mathbf{u}N = \mathbf{v}.\tag{3.2}$$

First, we prove that  $\operatorname{sres}_j(M,R)$  is nonzero. Let  $N_d$  be the  $(m+n-2j)\times (m+n-2j)$  submatrix whose first (m+n-2j-1) columns are the same as those of N and whose last column is the (m+n-j-d)th column of N. Then  $\det(N_d)$  is the coefficient of  $t^d$  in  $\operatorname{sres}_j(M,R)$ . Hence, it suffices to prove that  $\det(N_d)$  is nonzero.

From (3.2) we see that

$$\mathbf{u}N_d = (\underbrace{0, \dots, 0}_{m+n-2j-1}, a_d). \tag{3.3}$$

Suppose that  $\mathbf{u}'=(c'_{n-j-1},\ldots,c'_0,\,b'_{m-j-1},\ldots,b'_0)$  is another solution of (3.3). Let

$$B' = \sum_{i=0}^{m-j-1} b'_i t^i, \quad C' = \sum_{i=0}^{m-j-1} c'_i t^i, \quad \text{and} \quad A' = C'M + B'R.$$

Then  $0 \le \deg_t A' \le j$  because of (3.3).

Equation (3.1) and the definition of A' give rise to the congruent equations  $BR \equiv A \mod M$  and  $B'R \equiv A' \mod M$ . Eliminating R from the two congruent equations, we get  $B'A \equiv BA' \mod M$ . Hence B'A = BA', since both  $\deg_t B'A$  and  $\deg_t BA'$  are less than m. Thus, B divides B' since GCD(A, B) = 1. Consequently, there exists h in  $\mathcal{F}$  such that hB = B', because  $\deg_t B'$  is not greater than  $\deg_t B$ . It follows that hA = A', so h = 1, because  $a_d$  is the coefficient of  $t^d$  in both A

and A'. Hence A = A', B = B', and, moreover, C = C'. We then conclude that  $\mathbf{u} = \mathbf{u}'$ , i.e., linear system (3.3) has a unique solution. Thus,  $\det(N_d)$  is nonzero.

By Lemma 7.7.4 in [32, p. 255], there are polynomials C'' and B'' in  $\mathcal{F}[t]$ , with  $\deg_t C'' \leq n-j-1$  and  $\deg_t B'' \leq m-j-1$ , such that  $C''M+B''R=\operatorname{sres}_j(M,R)$ . This equation and (3.1) give rise to the congruent equations  $BR\equiv A \operatorname{mod} M$  and  $B''R\equiv \operatorname{sres}_j(M,R) \operatorname{mod} M$ . The same argument as in the previous paragraph proves that A and  $\operatorname{sres}_j(M,R)$  are  $\mathcal{F}$ -linear dependent. Thus, A and  $\operatorname{sres}_j(M,R)$  are similar over  $\mathcal{F}$  because they are nonzero.

We recall some basic properties of the extended Euclidean algorithm (see, [20, Excercise 3 in §4.6.1]). Let  $A_1$  and  $A_2$  be in  $\mathcal{F}[t]$  such that  $\deg_t A_1 \geq \deg_t A_2 > 0$ . The extended Euclidean algorithm with inputs  $A_1$  and  $A_2$  generates three sequences (in  $\mathcal{F}[t]$ ):

$$A_1, A_2, \dots, A_r, U_1, U_2, \dots, U_r, \text{ and } V_1, V_2, \dots, V_r,$$

with the properties that, for  $i = 3, 4, \ldots, r$ ,

- 1.  $A_i$  is the remainder of  $A_{i-2}$  and  $A_{i-1}$ ;
- 2.  $U_iA_1 + V_iA_2 = A_i$ , where  $\deg_t U_i < \deg_t A_2 \deg_t A_i$  and  $\deg_t V_i < \deg_t A_1 \deg_t A_i$ ;
- 3.  $U_i$  and  $V_i$  are relatively prime.

The last property follows from the fact that  $U_{i-1}V_i - U_iV_{i-1} = \pm 1$ , for i = 2, 3, ..., r. We are ready to prove the correctness of the algorithm RECON<sub>f</sub>.

**Proposition 3.3.3** Problem RFR has a solution if and only if RECON with inputs M and R, returns a pair (A, B). If RECON returns a pair (A, B), then

$$AB^{-1} \equiv R \mod M$$
 and  $GCD(A, B) = 1$ .

**Proof** If  $\deg_t R \leq (\deg_t M)/2$ , then RECON\_f returns the pair (R,1). If  $\deg_t R \geq \deg_t M$ , then the residue R can be replaced by the remainder of R and M. We may then assume that  $(\deg_t M)/2 < \deg_t R < \deg_t M$ . Suppose that RECON\_f returns (A,B) in the ith iteration. Then we have  $BR \equiv A \mod M$ , because RECON\_f preserves the relation  $V_j R \equiv A_j \mod M$ , for  $2 \leq j \leq i$ , where  $V_j$  and  $A_j$  are produced by RECON\_f. Moreover, the relation  $GCD(V_i, A_i) = 1$  implies that  $GCD(V_i, M) = 1$ , according to the third property of the extended Euclidean algorithm. The pair (A, B) is the desired solution.

Conversely, let (A, B) be the solution to Problem RFR with GCD(A, B) = 1. Let  $M, R, A_3, \ldots, A_k$  be a PRS generated by the Euclidean algorithm. Then Lemma 3.3.2 implies that there is a non-zero element a in  $\mathcal{F}$  such that  $A = aA_l$ . We then have the following congruent equations:

 $BR \equiv A \mod M$  and  $aV_l R \equiv A \mod M$ ,

where  $\deg_t V_l < \deg_t M - \deg_t A_l$  by the second property of the extended Euclidean algorithm. Eliminating R from the above congruent equations, we get  $(aV_l - B)A \equiv 0 \mod M$ . Thus,  $aV_l = B$  since  $\deg_t (aV_l - B)A < \deg_t M$ . As the degrees of the  $V_j$ 's increase and the degrees of the  $A_j$ 's decrease in RECON f, the pair f(A,B) is found in the fth iteration.

Based on RECON\_n and RECON\_f we present the algorithms COEFF\_n and COEFF\_f that reconstruct the rational number and rational function coefficients of polynomials from the given residues, respectively. These two algorithms, together with CRA, will be used to combine modular and evaluation homomorphic images. As these two algorithms can be worked out easily, we only specify their inputs and outputs.

#### algorithm COEFF\_n

Input: A modulus  $m \in \mathbb{N}^+$  and a non-zero residue  $R \in \mathbb{Z}_m[t][X]$ .

Output:  $A \in \mathbf{Q}[t][X]$ , such that  $A \equiv R \mod m$  and the denominators and numerators of the rational coefficients in A range from  $-\sqrt{m/2}$  to  $\sqrt{m/2}$  if such a polynomial exists. Otherwise, NIL is returned.

#### algorithm COEFF\_f

**Input:** A modulus  $M \in \mathbf{Z}_p[t]$  with  $\deg_t M > 0$ , and a non-zero residue  $R \in \mathbf{Z}_p[t][X]$ .

Output:  $A \in \mathbf{Z}_p(t)[X]$ , such that  $A \equiv R \mod M$ ,

the denominators of the coefficients of A have degrees  $<(\deg_t M)/2$ , and the numerators of the coefficients in A have degrees  $\le (\deg_t M)/2$ , if such a polynomial exists. Otherwise, NIL is returned.

# 3.4 Modular Algorithm for Computing GCRDs over $\mathbf{Z}_p[t]$

Let  $(\mathbf{Z}_p[t][X], \sigma_p, \delta_p)$  be an Ore polynomial ring. We present the modular algorithm GCRD-p for computing GCRDs in this ring. We reduce the GCRD problem in  $\mathbf{Z}_p[t][X]$  to a series of problem of

computing the evaluation homomorphic images in  $\mathbb{Z}_p[X]$ , which will be later solved by the algorithm GCRD\_e. The "lucky" evaluation homomorphic images are combined by CRA and COEFF\_f. The termination of GCRD\_p is determined by trial division. It is a rare, though possible case that there are not enough lucky evaluation points in  $\mathbb{Z}_p$ . If this happens, GCRD\_p reports failure.

## algorithm GCRD\_p

```
Input: A prime p and A, B \in \mathbf{Z}_p[t][X] with \deg A \ge \deg B \ge 1.
    Output: C, where C = GCRD(A, B).
   [initialize the modulus, residue, and degree]
    1. k \leftarrow 0;
   2.
         repeat
                  if k = p then { report failure; } R_k \leftarrow \text{GRCD\_e}(p, k, A, B); k \leftarrow k + 1;
   3.
       until R_k \neq 0
   4.
      d_k \leftarrow \deg R_k;
      if d_k = 0 then return(1);
       M \leftarrow t - k; R \leftarrow R_k; d \leftarrow d_k; C \leftarrow 0;
  [main loop]
       while true do {
  8.
  9.
               repeat
                         if k = p then { report failure; } R_k \leftarrow GRCD_e(p, k, A, B); k \leftarrow k + 1;
  10.
  11.
               until R_k \neq 0
 12.
               d_k \leftarrow \deg R_k;
               [ test for unlucky evaluation points ]
 13.
               if d_k < d then goto line 7;
 14.
              if d_k = d then {
                 [combine]
                R \leftarrow \text{CRA}(R, M, R_k, t - k); M \leftarrow (t - k)M;
15.
16.
                \bar{C} \leftarrow \text{COEFF} f(M, R);
17.
                if C \neq 0 and C = \tilde{C} then
                   [trial division]
18.
                   if A \equiv 0 \mod C and B \equiv 0 \mod C then return(the numerator of C);
19.
               C \leftarrow \bar{C}; \}
```

Section 3.5. Modular Algorithm for Computing GCRDs over  $\mathbf{Z}[t]$ 

Proposition 3.4.1 The algorithm GCRD-p is correct.

Proof Let G be GCRD(A, B) with degree l. If l = 0, then  $GCRD_p$  returns 1 when there exist a lucky evaluation point in  $\mathbb{Z}_p$ . From now on, assume l > 0. If there are less than (2l + 2) luck points in  $\mathbb{Z}_p$ ,  $GCRD_p$  reports failure. Assume that there are more than (2l + 1) lucky points in  $\mathbb{Z}_p$ . Then the tentative degree d in  $GCRD_p$  will be eventually equal to l, because, for each unlucky point,  $GCRD_p$  returns either 0 or a polynomial of degree greater than l. Unlucky evaluation points can be detected in line 13 as soon as a lucky one is encountered. So we may suppose that d is equal to l. Then each l0 mod l1 in l1 ine 15 is equal to l2. Hence l2 l3 mod l4 in l4 in l5 is equal to l5 recovers l6 mod l8 in l9 reposition 3.2.1. Hence l9 l9 l9 mod l9 mod l9 in l1 in l1 ine 16 recovers l1 l1 when deg l1 l1 exceeds 2l2. COEFF l1 produces l3 gain when the next lucky evaluation point is encountered. At this point the condition l4 l5 in line 17 is satisfied. Hence l6 after a trial division.

The next lemma ensures that GCRD-p does not report failure if p is sufficiently large.

**Lemma 3.4.2** If A and B are in  $\mathbb{Z}_p[t][X]$ , with respective degrees m and n, where  $m \geq n \geq 1$ , then there are at most

$$\deg_t \left( \prod_{i=0}^{m-1} \sigma_p^i(\operatorname{lc}(B)) \right) + m \deg_t B + n \deg_t A \tag{3.4}$$

unlucky evaluation points for A and B.

**Proof** If k is unlucky for A and B, k is a root of

$$\left(\prod_{i=0}^{m-1}\sigma_p^i(\operatorname{lc}(B))\right)\operatorname{lc}(\operatorname{sres}_d(A,B)),$$

where d is the degree of GCRD(A, B), and (3.4) gives a degree bound for this polynomial.

# 3.5 Modular Algorithm for Computing GCRDs over $\mathbf{Z}[t]$

In this section, we let A and B be in  $\mathbf{Z}[t][X]$  with respective degrees m and n, where  $m \geq n \geq 1$ . Assume that  $G = \mathrm{GCRD}(A, B)$  with degree k. Using modular homomorphisms we reduce the problem of computing G to a series of the problems of computing the monic associates of the modular homomorphic images of G. First, we define unlucky primes.

**Definition 3.5.1** A prime p is unlucky for A and B if one of the following holds:

- 1. p is a divisor of  $hc(\sigma(t))lc(A)lc(B)$ ;
- 2. p is a divisor of  $lc(sres_k(A, B))$ ;
- 3. p is a divisor of hc(G);
- 4.  $\phi_p(G)$  is not primitive with respect to X.

**Lemma 3.5.1** If p is not unlucky and  $\mathbf{Z}_p[t][X]$  is the induced Ore polynomial ring from  $\mathbf{Z}[t][X]$  by the modular homomorphism  $\phi_p$ , then

$$GCRD(\phi_p(A), \phi_p(B)) = \phi_p(G)/\phi_p(hc(G)).$$
(3.5)

**Proof** As  $\deg A = \deg \phi_p(A)$ ,  $\deg B = \deg \phi_p(B)$ , and  $\phi_p$  is an Ore ring homomorphism, we see that  $\mathrm{sres}_k(\phi_p(A),\phi_p(B)) = \phi_p((\mathrm{sres}_k(A,B)) \neq 0$ . So the degree of  $\mathrm{GCRD}(\phi_p(A),\phi_p(B))$  is not greater than k, since every common right factor of A and B must be a right factor of their subresultants. On the other hand, Corollary 3.1.3 implies that  $\phi_p(G)$  is a common right factor of  $\phi_p(A)$  and  $\phi_p(B)$ . Thus,  $\phi_p(G)$  is a GCRD of  $\phi_p(A)$  and  $\phi_p(B)$ , because  $\deg \phi_p(G) = k$ . Hence (3.5) holds because  $\phi_p(G)$  is primitive with respect to X.

Clearly, there are only finitely many unlucky primes for A and B. For each lucky prime p,  $\phi_p(G)/\text{hc}(\phi_p(G))$  can be obtained from  $\text{GCRD}(\phi_p(A),\phi_p(B))$  by Lemma 3.5.1. These considerations lead to the algorithm  $\text{GCRD}\_m$ .

### algorithm GCRD\_m

Input:  $A, B \in \mathbf{Z}[t][X]$ .

Output: C, where C = GCRD(A, B).

## [initialize]

- 1. if  $deg(A) \ge deg(B)$  then  $\{A_1 \leftarrow A; A_2 \leftarrow B; \}$
- 2. else {  $A_1 \leftarrow B; A_2 \leftarrow A; }$
- 3.  $A_1 \leftarrow \text{the primitive part of } A_1 \text{ w.r.t. } X;$
- 4.  $A_2 \leftarrow \text{the primitive part of } A_2 \text{ w.r.t. } X;$
- 5.  $b \leftarrow hc(A_1)hc(A_2)hc(\sigma(t));$

[initialize the modulus, residue, and degrees]

6.  $p \leftarrow a$  large prime not dividing b;

```
7. R_p \leftarrow \text{GCRD-p}(p, \phi_p(A_1), \phi_p(A_2));
   8. D_p \leftarrow \deg R_p; d_p \leftarrow \deg_t R_p;
   9. if D_p = 0 then return(1);
   10. m \leftarrow p; R \leftarrow R_p; D \leftarrow D_p; d \leftarrow d_p; C \leftarrow 0
   [main loop]
   11. while true do {
  12.
                  p \leftarrow a new large prime not dividing b;
  13.
                  R_p \leftarrow \text{GCRD-p}(p, \phi_p(A_1), \phi_p(A_2));
  14.
                  D_p \leftarrow \deg R_p; d_p \leftarrow \deg_t R_p;
                  [ test for unlucky primes ]
  15.
                 if D_p < D then goto line 9;
                 if D_p = D and d_p > d then goto line 10;
 16.
                 [combine]
 17.
                 if D_p = D and d_p = d then {
                    R \leftarrow \text{CRA}(R, m, R_p, p); m \leftarrow pm;
 18.
                   \tilde{C} \leftarrow \text{COEFF\_n}(m, R);
19.
                   if C \neq 0 and C = \bar{C} then
20.
                      [ trial division ]
21.
                      if A_1 \equiv 0 \mod C and A_2 \equiv 0 \mod C then return(the numerator of C);
22.
                   C \leftarrow \bar{C}; \}
```

Remark 3.5.2 By "large prime" p, we mean that p is so large that GCRD\_p does not report failure. It is always possible to choose such p by Lemma 3.4.2.

Proposition 3.5.2 The algorithm GCRD\_m is correct.

**Proof** As b is assigned to be  $hc(A)hc(A)hc(\sigma(t))$  in line 5, GCRD-p can only result  $R_p$  in lines 7 and 13 such that either  $\deg R_p > \deg G$  or  $\deg_t R_p < \deg_t G$  if p is unlucky. Unlucky primes can be detected in lines 15 and 16 as soon as a lucky prime is encountered. Since there are only a finite number of unlucky primes, we may further assume that  $D = \deg G$  and  $d = \deg_t G$ . Accordingly, the polynomial R in line 18 satisfies the congruence  $R \equiv G/hc(G) \mod m$  by Lemma 3.5.1. Then the polynomial  $\bar{C}$  computed by COEFF-n in line 19 is equal to G/hc(G) as soon as  $\sqrt{m/2}$  exceeds the absolute value of the maximum of the integral coefficients of G. Thus, GCRD-m returns G.  $\Box$ 

The advantages of GCRD\_m are clear. The problem of finding GCRD(A, B) is mapped to the domains in which the arithmetic does not cause any intermediate swelling. In addition,  $GCRD_m$  can recognize the case when GCRD(A, B) is trivial as soon as a lucky prime is encountered.

## 3.6 Experimental Results

This section presents experimental results to compare the algorithm GCRD\_m, subresultant algorithm, and primitive Euclidean algorithm. We implemented in  $Maple\ V$  (Release 3) these three algorithms for the differential operator D and shift operator E with coefficients in  $\mathbf{Z}[t]$ , where D and E are defined in Examples 2.2.2 and 2.2.3, respectively.

The first suite was generated as follows. We used the Maple function randpoly to generate pairs of bivariate polynomials in  $\mathbf{Z}[t,X]$ , with total degree n and n-1, where  $n=5,\,10$ , and 15. These polynomials had five terms with coefficients ranging from -99 to 99. We then regarded these polynomials as differential operators in  $\mathbf{Z}[t][D]$  and shift operators in  $\mathbf{Z}[t][E]$ , respectively, and computed the GCRD of each pair. The timings are summarized in Figure 3.1, in which the column labeled n gives the total degrees of the polynomials; the columns labeled DM, DS, DPE, give the respective computing times for GCRD\_m, the subresultant algorithm, and primitive Euclidean algorithm whose inputs are differential operators; similarly, the columns labeled SM, SS, SPE, give the respective computing times for GCRD\_m, subresultant algorithm, and primitive Euclidean algorithm whose inputs are shift operators. All the entries are Maple CPU time and given in seconds.

n	DM	DS	DPE	SM	SS	SPE
5	0.20	0.27	0.19	0.17	0.25	0.21
10	0.99	38.86	39.71	0.59	42.73	40.71
15	1.65	301.25	374.00	0.77	436.47	485.91

Figure 3.1: Computing times for the first suite

We see from Figure 3.1 that GCRD\_m is considerably faster than non-modular ones when input polynomials are of total degree more than eight. This is not a surprise since the GCRD of two random polynomials is usually trivial. In practice, GCRD\_m can detect the case when input polynomials have a trivial GCRD by one or two primes. The timings also indicate that the subresultant algorithm is slightly faster than the primitive Euclidean algorithm when input

polynomials are chosen at random.

To construct the second suite, we used randpoly to generate three polynomials, say, A. B. and C in  $\mathbf{Z}[t,X]$ , with respective total degrees n-2, n-3, and 2, where n=5, 10. and 15. The number of terms and length of coefficients were the same as those in the first suite. We took the differential (shift) products AC and BC as input polynomials. Thus, the GCRD of each pair of input polynomials was usually nontrivial. The timings are summarized in Figure 3.2. where a dash (-) indicates that our implementation of the primitive Euclidean algorithm took more than three hours without any output. This could happen because it took very long time to compute the primitive part of a polynomial in  $\mathbf{Z}[t][X]$  when the content had large integral coefficients.

n	DM	DS	DPE	SM	SS	SPE
5	2.26	0.25	0.15	1.29	0.30	0.15
10	9.91	64.25	16.72	3.74	57.66	18.67
15	27.23	1348.83	-	6.46	1999.64	-

Figure 3.2: Computing times for the second suite

Again, the timings in Figure 3.2 indicate that GCRD\_m is more efficient than non-modular ones. We also remark that the subresultant algorithm may be slower than the primitive Euclidean algorithm when input polynomials have a non-trivial GCRD. This is because the primitive Euclidean algorithm removes more extraneous factors after each division when the GCRD is not monic (see. Theorem 2.2.8).

#### Ziming Li

Research Institute for Symbolic Computation (RISC-Linz)

Johannes Kepler University, A-4040 Linz, Austria

Phone: +43 7236 3231 26, Fax: +43 7236 3231 30

Email: zmli@risc.uni-linz.ac.at

#### Personal

Born June 6, 1962, Beijing, China. P. R. China citizen.

#### Education

M.S., Institute of Systems Science, Academia Sinica, Beijing, 1988 B.S., Department of Applied Mathematics, Tsinghua University, Beijing, 1985.

#### **Positions**

2/92- Research assistant, RISC-Linz, Austria.

7/88-1/92 Lecturer, Department of Applied Mathematics, Tsinghua University, Beijing.

#### Journal Publications

- Computations with Rational Parametric Equations (with S.C. Chou and X.S. Gao), Computer Mathematics, 86-111, World Scientific Pub., River Edg. NJ, 1993.
- Mechanical Theorem Proving in the Local Theory of Surfaces, Annals of Mathematics and Artificial Intelligence, 13, 25-46. 1995.

#### Conference Papers

- Finding Roots of Unity among Quotients of the Roots of an Integral Polynomial (with K. Yokoyama and I. István), in Proceedings of the 1995 International Symposium on Symbolic Computation, 85-89, ACM Press, 1995
- An Implementation of the Characteristic Set Method for Solving Algebraic Equations, in Proceedings of the PoSSo Workshop on Software, Paris, 1995, to appear.

#### **Technical Reports**

- A Subresultant Theory for Linear Differential Polynomials, RISC-Linz Technical Report, no. 95-35, 1995.
- A Construction of Radical Ideals in Polynomial Algebra (with J. Schicho), RISC-Linz Technical Report, to be available.
